INDEX.

Throughout the Index the following abbreviations are used to indicate the nature of the subject matter:—

(Pat.) Patent News. (Cor.) Correspondence. (Soc.) Societies' Meetings. (Rev.) Review or Trade Notice.
(Ans.) Answers. (Anal.) Analecta.

The Index includes several Sub-Indexes—

Bankruptcies. Books Reviewed. Companies Registered. Deaths. Exhibitions. Names and Marks. Trade.
Patents (Authors of).

which are placed in their alphabetical positions.

Subject Index.

For Names of Authors of Articles and Papers, see Authors' Index, p. VI.

A

Accident prevention, use of photographs. By G. D. Crain, Junr., 635
Acetic acid substitute in wet-plate developer (Cor.), 226
Actinometer, multiple-type, making, 46
Advertising the studio. By Practicus, 263
— photo-engraved novelties for, 355
Aerial, American, Photography Association, 342
Aerial cameras, British, progress in war-time, 139
— evolution during war. By C. M. Williamson, 309
— A. Brock, Junr. (Pat.), 506, 507
— G.E.M. Engineering Co. (Pat.), 477
— F. C. V. Laws (Pat.), 299
— moving, E. Duerr (Pat.), 237
— stereoscopic, D. A. English (Pat.), 535
— Thornton-Pickard. By S. L. Hughes, 293
— Williamson (Pat.), 323, 324
— H. Workman (Pat.), 131
— photographs, mapping from. By M. N. MacLeod, D.S.O., 503, 518
— photographic supplies for sale, 523
— photogrammetry, present position surveyed. By Major P. R. Burchall, R.A.F., 695
— and Ordnance Survey, 655, 685
— photography and town planning (Cor.), 18
— angling, admissible limit, in vertical or horizontal photography. By L. P. Clerc, 297
— correction of negatives taken obliquely. By L. P. Clerc, 306, 411, 428, 449
— development of British lenses for, 133, 243, 264
— during the war, 39, 148, 211, 349
— estimating height of object by measurement of cast shadows. By L. P. Clerc, 295
— horizon line, lowering. By L. P. Clerc, 295
— in the future. By A. Brock and L. J. R. Holst, 87, 106
(See also *Royal Flying Corps*.)
Aerial Photos, Ltd., commercial aerial photography, 727
Aeroplane post and photography, 421
Affiliation outing to Croydon, 286, 342, 374
Air raids on London photographers' premises, 143
Airbrush in advertisement work, 88
Allies Studios, limited partnership, 478
Aluminium, soldering with Kavalin (Soc.), 609
Amateurs' work, finishing, 191
American Aerial Photography Association, 342
Amidol developer, Piper formula, 713
— v. M.Q. for bromides, 75
— Griffins (Rev.), 554
Anti-sulphuric paint for labelling bottles, 552
Apparatus, minor repairs to, 258
Appearances of studio and staff, value of, 66
Apprenticeship, report of the Edinburgh Society of Professional Photographers, 609
Artificial lighting, merits of various types. By Practicus, 59
Assistant photographers'. By D. Charles, 142
Assistants, association for (Cor.), 403, 419, 446, 462
— discussion of conditions (Cor.), 7, 18, 31, 43, 55, 63, 78, 91, 119, 135, 150, 167, 227, 643, 655, 670, 686, 703, 714
— education of, 82
— wages (Cor.), 393, 343, 358, 375
Athey and Sykes, partnership dissolved, 609

B

Baby portraits, obtaining orders, 458
Backgrounds in the portrait studio. By Practicus, 86
— natural, Elwin Neame, 482, 754
— two early methods, 528
— on negatives, reducing, 711
— white, rear lighting, 327
Backing, quinine, for plates, 286
Balance, G. R., removing to France, 509
Bas-relief effects in enlargements, 547

BANKRUPTCIES—

Barron, R. C., 642, 655, Louvre Studios, Ltd., 433, 701
Bramwell, J. E., 445, Michell, C. F., 165, 179
579, Morrison, P. and T., 433
Croft, J. P., 701, Newman, T. F., 387
Curtis, W., 462, Noakes, A. A., 568, 642
Empire Studios, 254, 235, Power, P. E. le Poer, 225
Gray, M. J., 254, 285, Priest, A. E., 434, 509
Gray, F. W., 285, Roffey, A., 701
Heathcote, H. A. Y., Siedle, C. F., 445, 579, 655
Jones, H. A., 43, 194, Soward, F., 554, 669
494, Thorne, H. S., 434, 523
Beach photographers fined, 507, 537
Bellfast, photography in strike time, 62
Bellows, renovating, 409
Bichromate-mercury intensifier for negatives. By D. Charles, 172
Bioscope, origin of word (Cor.), 107
Bisecting rule for centering mounts and mount outting. By V. Jobling, 622
Bleach-out process (Cor.), 28
Blinds and curtains for the studio. By Practicus, 530
— festoon, fitting, 657
Blocked-out negatives, substitute for opaque, 711

BOOKS REVIEWED.

Chemical Dictionary, The Condensed, 640
Chemical Reagents, 554
Chemist and Druggist Diary, 16
Design in Picture Making by Photography, 683
Elements of Photography. By F. R. Fraprie, 507
Figures, Facts, and Formulae, More, 146
Hands in Portraiture, 6
Home and Garden Portraiture, 507
Kelly's Directory of the Chemical Industries, 1919, 553
Marvels of Photography. By C. R. Gibson, 598
Photograms of the Year, 6
Stereoscopic Photography, 553
Theory of Modern Optical Instruments. By Dr. A. Gleichen, 177
Wonders of the Seashore. By F. Martin Duncan, 16
Boot accessory for child portraiture (Rev.), 508
Border tints, printed-in, and masked prints. By E. A. S., 314
British and Colonial Camera Club, formation, 555
British Industries Fair, fifth, 101
British Journal offices in enemy air-raids, 1
— price raised to threepence, 733
British Photographic Manufacturers' Association, annual meeting, 726
Broddick photographic apparatus, 219
Broken negatives, repairing, 235
Bromide, paper, amidol v. M.Q. developer, 75
— de luxe, cream carbon, double-weight, Illingworth (Rev.), 325
— hard-grade Press, Criterion (Rev.), 728
— portrait, Criterion (Rev.), 325
— time development, 257
— transfer, Kerotype, Ltd. (Pat.), 400
— demonstrations, 16, 127, 254
Bromide printing, past and present. By C. B. Barnes, 204
— By Practicus, 707
— prints, fixation, 198, 226, 239
— fixing bath to stain on ceasing to fix, 230
— purple tones by re-development (Cor.), 63
— By E. Manley, 123
— sepia toning, localised, 645
— toning processes compared, 748
Bromoil portraits, F. T. Usher (Rev.), 194
Bromoids, hand-engraved for copper-plate effects, 630
— negative (Cor.), 714
Bronzed complexion, photographing, 466
Butcher-Williamson cinematograph arrangement, 402
Business methods in the studio. By Practicus, 201
— pitfalls, 230
Businesses, Retail, Licensing Order, administration changes, etc., 149, 225, 706

C

Callotype, photo-mechanical reproduction of type-writing, 690
Cameras and lenses for studio. By Practicus, 11
— and plates, small, new standard sizes, 214, 220, 239, 255, 270, 274
— focal-plane, British Anschutz, Peeling and Van Neck (Rev.), 667
— roll-film, Thornton-Pickard Mfg. Co., 339
— folding, Newton and Wright, Ltd. (Pat.), 269
— S. P. Twemlow (Pat.), 355
— hand, for professionals, 698
— — By Practicus, 368
— movements. By D. Charles, 331, 348, 364
— panoramic, N. Stefani (Pat.), 163
— photogrammetric, N. Stefani (Pat.), 477
— roll-film, G.E.M. Engineering Co. (Pat.), 552
— S. P. Twemlow (Pat.), 268
— studio, Salex City Sale (Rev.), 640
— vest-pocket, advantages in commercial work, 390
— — specifications for. By E. L. C. Morse, 234
(See also *Vest-pocket*.)
— with mechanical plate changing, Thornton-Pickard Mfg. Co. (Pat.), 536
(See also *Aerial Cameras, Reflex Cameras*.)
Camouflage, detection by photography, 594
Canvas, sensitising (Cor.), 594
— silver grey tones (Cor.), 643
Carbon printing. By Practicus, 675, 692
— by artificial light. By S. S. Richardson, 35
— strip tests, 10
— tissue, non-sensitiveness to fumes, 170
— sensitising, 242
Carbro (Ozobrome) printing process. By H. F. Farmer, 583
— demonstration at Croydon, 758
— at R.P.S., 729
Card index system for orders (Cor.), 594
Carvacrol, para-amino-, developer, preparation. By H. A. Lubs, 534
Catford, A., representing Messrs. Houghtons, 537
Cats, photography of, 131
Cecil, Hugh, and excess profits tax, 750, 754
Celluloid, emulsion-coating, N. L. Scott (Pat.), 41
Celluloid—facing of miniatures, 102
Changing bag, home-made (Cor.), 195
— boxes, C. Rothmeyer (Pat.), 236
Changing studios and businesses. By Practicus, 659
Chemical Dictionary, The Condensed (Rev.), 640
Chemical Industries, Kelly's Directory of, 1919, 553
Chemical Reagents (Rev.), 554
Chemicals, dyed, A. de Brayer (Pat.), 177
— economy in, 58
— storage, 411
Children, photographing. By Practicus, 312
— studios advertising to. By E. A. Dench, 710
China, trade marks in. By W. B. Kennett, 664
Christmas portrait business, timely preparations, 652
Chromium intensification with chlorochromates. By A. and L. Lumière and A. Seyewetz, 451
— followed by mercury. By D. Charles, 172
— hydrobromic acid bleach. By R. E. Crowther, 709
Cinematograph camera, making money with. By E. A. Dench, 661
— films, developing and drying. F. B. Thompson (Pat.), 162
— reinforced, H. Degens (Pat.), 237
— spools, A. Laban (Pat.), 401
— picture-films for schools, Hudson's Bay Company's project, 597
— lettered, S. A. Flower (Pat.), 208
— permanent collections, 402
— speaking, reported Swedish invention, 638
— night effects. By R. Dykes, 528
— or kinematograph (Cor.), 78, 90, 119, 134, 150
— shutters, H. Shorrocks (Pat.), 299
— A. G. Smith (Pat.), 283
Cinematography, colour, L. F. Douglass (Pat.), 16
— J. Shaw (Pat.), 356
Clock, dark-room, constructing, 161
Closing of studios, holiday. See *Holiday closing*.
Club photography, a copyright point, 230
Coal, gas, and electricity, continued rationing, 357

Cohen and Loveton, dissolution of partnership, 238
 Coles and Crane, partnership dissolved, 563
 Colour, books on, 57
 Colour cinematography (Pat.), 16, 386
 — digest of recent processes, 27
 — fourteen points on. By A. V. Godbold, 261, 275
 — photography and cinematography (Gorski and Rodgers and Finnigan), 537
 — composite mosaic and full-tone process, Hess-Ives Corporation (Pat.), 61
 — copper and iron toning, Hess-Ives Corporation (Pat.), 578
 — mosaic imbibition process, H. Pedersen (Pat.), 61
 — two-colour process, Friese-Greene (Pat.), 728
 — screen-plate, Dufay, 606
 — — J. T. Smith (Pat.), 712
 — sensitive units for J. H. Christensen (Pat.), 692
 — transparent sensitive emulsion for three-colour films, J. H. Christensen (Pat.), 639
 Colour-sensitive emulsions, F. F. Renwick and another (Pat.), 600
 Colour-sensitizer for two-colour process, Friese-Greene (Pat.), 728
 Colour values in monochrome, and a new viewing filter. By F. F. Renwick, 354, 351
 Colouring photographs, J. MacDougal (Pat.), 682
 Combination printing, 608
 — By Practicus, 547
 Commercial photographs, county court claim, 444
 — soft-focus, 461
 Commercial photography of difficult metal subjects
 By R. B. Lockwood, 217
 — price policy. By G. D. Crain, Junr., 602
 Commission system for receptionists. By N. Barrie, 37

 Secretan, G. W., 149
 Strong, Henry A., 505
 Webster, G. Watmough, 169
 Welford, Walter D., 474
 Willis, H. J. B., 43

Defects, tracing, in negatives, 514
 Density of negatives, photometer for comparison. By H. W. G. Bidgood, 637
 Desensitizers and development papers. By W. C. Mann, 626
 Design in Picture Making by Photography (Rev.), 682
 Developer and fixer combined for ferrotype plates (Cor.), 195
 — Hochstetter's patent, 14
 Developers, comparison as regards various working properties, 727
 Developing and printing for amateurs, prices (Cor.), 444
 — formulae, alternative chemicals. By J. I. Crabtree, 389
 — solutions, how to mix. By J. I. Crabtree, 389
 — tanks, J. P. Hemen (Pat.), 563
 Development, complete, of bromides, test for, 121
 — negative, 154, 306
 (See also *Yank Development*.)
 Diagrams, enlargements of, for use in schools, 573
 Diffused prints from sharp negatives, 576
 Diffusing media, absorption variations, 607
 — screens, in supplementary control of lighting, 698
 Dishes, coatings for, 574
 Distorted photographs, lens for, W. H. Baker and another (Pat.), 236
 Distortion, lens, in copying, avoiding, 45
 Dividing light-pencils, prism and grid for, D. F. Comstock and another (Pat.), 472
 Double exposures, preventing (Cor.), 510
 Drawing, self-training, 569
 Dry-mounting tissue, Akon (Rev.), 198
 — with a copying press (Cor.), 419
 Drying cabinet for negatives (Cor.), 594
 — X. L. Brodick (Rev.), 223
 — prints, machine, S. H. Morse (Pat.), 163, 744
 — with spirit: cause of white deposit. By L. P. Carr, 250, 273
 Dufay colour screen-plate, 606
 Dye-chemicals, A. de Braver (Pat.), 177
 Dye-toned images, F. E. Ives (Pat.), 6
 Dye-toning of lantern slides, 598

E

Eastman Research Laboratory, war work, 715
 — yellow, new dye for light filters, 43
 Eder, Dr. J. M., biographer of Schulze, 594
 Edinburgh Societies of Professional Photographers, meetings, 42, 49, 147, 209, 341, 419, 609, 664
 — annual dinner, 739
 — visit Glasgow, 654
 Education of assistants, 62
 Efficiency in the workshop. By H. G. Stokes, 575, 584, 603
 Electric bulbs, colouring and frosting, 179
 Electricity and photography in warfare (portable generating plants). By H. Morse, 113
 — power rate for photographers, Edinburgh (See), 662
 Elements of Photography (Rev.), 507
 Elton George, photographic record of scenes in the life and writings of, 619
 Embossing board for mounts and prints, 607
 Emulsion coating of celluloid, N. L. Scott (Pat.) 41
 Emulsions, sensitive, transparent, J. H. Christensen (Pat.), 620
 Enns patents and trade marks, 401
 Engineers, Royal, photography with, in wartime, 102

Enlarged negatives, methods of making, comparative notes, 467, 498
 Enlargements, canvasser sentenced, 579
 — for finishing, 9
 — negatives filling standard-size papers, 251
 — of diagrams for teaching purposes, 573
 — vignettted and diffused, fitting for lantern stage. By A. Henderson, 720
 Enlarging and copying, postcard lantern as an aid, 174
 — and grain, 242
 — and printing room, arranging, 575
 — and reducing in true-to-scale processes. By D. Charles, 736
 — advantage of interchangeable condensers, 557
 — apparatus, P. Boucard (Pat.), 461
 — daylight, estimating exposure, 399
 — easels, H. W. Moyne (Pat.), 324
 — holder for bromide paper (Cor.), 446
 — lantern, projection lenses of various focal lengths. By A. Henderson, 720
 — — Salex, City Sale (Rev.), 653
 — methods and novelties. By F. B. Howe, 546
 — soft effects. By J. W. Doubleday, 153
 Envelopes for films and plates, J. P. Hansen (Pat.), 623

Etching effects in enlargements, 547
 Etching time, standardising in photo-engraving, 370
 Evidence, legal, photographs as. By La Verno T. Ryder, 276
 Examinations, City and Guilds of London, change of programme, 657
 — questions in pure photography, 336
 — questions in photo-mechanical processes, 353
 Excess profits tax, judgement against Hugh Cecil, 730, 734

Hands in Portraiture (Rev.), 6
 Hardener, Tropical, Ilford, Johnson (Rev.), 325
 Hardening bath for tropics, A. J. Agnew and others (Pat.), 460
 Hare, G., hand-camera pioneer, 1
 Head in portraiture, posing. By Practicus, 423
 Heating and ventilating the studio, 111
 Heawood and Watson, partnership dissolved, 669
 Hectograph copying, ink formula, 554, 570
 — jelly for duplicating (Soc.), 554
 Heron, M., and Wechsler, A., partnership dissolved, 105
 High-temperature development, A. J. Agnew and others (Pat.), 460
 Holiday closing of studios (Cor.), 358, 446, 462, 479
 Home and Garden Portraiture (Rev.), 507
 Home portraiture. By C. H. Davis, 453
 — (Foister Brigham), 71
 — By Practicus, 172
 Horseback portraits in Hyde Park, tenders invited, 621
 Hudson's Bay Company, financial supporters of school cinema films, 597
 Hydrometer test of solutions, 366
 Hydroquinone-Rodinal developer, 79, 80
 Hygiene in the dark-room, 139
 Hypo solution, making without weighing (Soc.), 117
 Hypo-alum toning bath, metal dishes (Cor.), 447, 462
 — v. sulphide toning (Cor.), 579

I

Identification outfit, F. and S. Kodak (Rev.), 76
 Ilford, Ltd., dividend, 713
 Import regulations, photographic goods, 274, 450, 469, 498
 — declared illegal. Sankey judgment, 749
 — in Anti-Dumping Bill, 690
 Importation of paper without licence, 522
 Intensification and reduction of negatives (Soc.), 166
 — chromium, with chlorochromates. By A. and L. Lumière and A. Seyewetz, 451, 700

Intensification, chromium, modified formula, 67
 — mercury. By D. Charles, 172
 — portrait negatives. By Practicus, 439
 — with pyro developer. By R. S. Wiley, 721
 Intensifiers, organic, 181
 Iodine-cyanide reducer, compounding, 57

K

Kallitype prints, permanence of, 685
 Kathol-hydroquinone developer, 741
 Kentmere, Ltd., new London agent, 302
 Keogh v. Leventhal, copyright infringement judgment, 414
 Kerotype transfer bromide and gaslight papers, 16, 127, 254, 400
 Kitchener, Lord, historic photographs by, 626
 Kodak (Australasia), Ltd., increasing profits, 250
 Kodak, Eastman, Company, annual report, 443
 — dividends, 92, 270, 419, 509, 602, 684
 — share-holding scheme for employees, 220
 — war memorials unveiled, 702
 (See also Eastman.)
 Krupps, report of camera-making, 639

L

Labour shortage and its effects in American photo-engraving, 476
 Labeling bottles, 552
 Lancashire and District Master Photographers' Society, annual dinner, 62, 118
 — exhibition (Soc.), 343
 — meetings, 373, 433, 668
 — officers, 342
 Lan-Davis, C. F., will of the late, 91
 Lantern, projection, with extra short-focus objective. By A. Henderson, 720
 — screens, J. Chantave (Pat.), 145
 — H. R. Gilpin (Pat.), 477
 — H. Harris (Pat.), 536
 — F. Heale and another (Pat.), 177
 — C. F. Kirby (Pat.), 41, 177
 — postcard, in copying and enlarging. By A. Lockett, 174
 Lantern-slides, announcement, R. G. Elder (Pat.), 206
 — dye-toning, review of recent processes, 598
 — of cine. film-pictures, F. W. Perkins (Pat.), 208
 — making, personal practice in, Dudley Johnston, 25
 Large proofs as business getters, 75
 Latent image, recent research, 27
 Laws, Major F. C. V., permanent commission, 462
 Leaky studio rooms. By Practicus, 515
 Legal photography. By La Verne T. Ryder, 276
 Lens, air-space stigmat, A. A. Smith (Pat.), 689
 — apertures, measuring, 450
 — cells, stuck, tool for removing, 608
 — distortion from, in copying, avoiding, 45
 — for distorted photographs, W. H. Baker and another (Pat.), 236
 — triplet large aperture, A. Taylor and others (Pat.), 430
 Lenses, British, opinions and criticisms (Cor.), 569, 579
 — and German, need of propaganda, 2
 — for aircraft photography, development. By W. B. Appleton, J. Hasselkus, and Aldis Bros., 243, 264
 — buying, considerations in, 231
 — cleaning, chamois bag for, 711
 — flare, avoiding, 46
 — for portraiture. By Practicus, 232, 349
 — quartz of f/4 aperture, 717
 — second-hand, caution to buyers (Cor.), 627
 — colour, 121
 — special, for odd jobs, 94
 — testing for process and copying work. By E. K. Hunter, 565
 (See also *Soft-focus Lenses*, *Telephoto Lenses*.)
 Licenses for retail businesses. (See *Retail Businesses* (Licensing) Order.)
 Light-filters from new yellow dye, 48
 — making (Soc.), 477
 Light-filters, Wratten M., 18
 Lighting and tone in portrait photography, 424
 — in portraiture. By Practicus, 3
 Likeness in portraits, some critics on, 558
 Lithographic transfers from bromide prints. By J. Graham, 188
 Liver of sulphur for toning bromides, 169
 Liverpool, photographers' club (Cor.), 509, 642

— proposed increase of subscription, 708
— meetings—
Aerial photography, Major F. C. V. Laws, 340
Carbon printing. Dr. C. Atkin Swan, 263
Carbro (Dibromide) process. H. F. Farmer, 729
Cathedrals of Ely, Lichfield, Gloucester, and Wales, W. J. Roffey, 237
Colour values in monochrome and a viewing filter as an aid to obtaining them, F. F. Renwick, 224
Commercial photo-copying processes, K. Bakorsell, 175
Development papers and desensitizers, 269
Discussion on the formation of a scientific group, 193
English fonts from Saxon times to the sixteenth century, B. Gardner, 61
Egypt: its antiquities and people. R. H. Goodsell, 165
Fancy lighting in portraiture. N. E. Luboshez, 745

Finishing bromide prints, N. F. Horne, 146
Hints and suggestions for use in the dark-room, V. Jobling, 117
Home of the Rajput, 284
Hurter and Driffield's work, J. W. Gordon, K.C., 30
Kerotype paper, F. W. Kent and T. P. Middleton, 16
King's Highway, A. H. Blake, 641
Lenses for aerial photography, W. B. Appleton, J. Haasokus and Aldis Bros., 133
NO and other things Japanese, C. P. Crowther, 701
Photographic evidence for the formation of stars from nebulae (Traill Taylor lecture), Rev. A. L. Cortie, 625
Presidential address, 52, 668
Printing on paper in natural colours, S. H. Williams, 88
Raydex three-colour printing, F. R. Newens, 653
Spiders, their structure and habits, Dr. G. H. Rodman, 301
West of England Notes, G. Avenell, 104
— scientific and technical group, 651, 755
Rubber stamps for mounts and stationery, 22

S

Salon, London, of Photography, announcement, 214
— portraits and figure work, 544
— By F. C. Tilney, 560
— marking the prints, complaint (Cor.), 358
Schulze, the discoverer of photography? 598
Second-hand apparatus, buying, 362
— lenses, caution to buyers (Cor.), 627
Self-toning paper, over-printed, remedying, 21
— securing good tone, 474
Separators, plate, home-made, for dish development (Soc.), 117
Sepias by sulphide toning, failures and causes. By Thermit, 563 (See also *Sulphide Toning*.)
Sheffield and district Professional Photographers' Association meeting, 469
Shew, J. F., and Co., proprietorship, 730, 743
Shock-absorbers for cameras. W. J. Greer (Pat.), 476
Shops Act, photographer's contravention, 117
Shutters, studio, improvements suggested, 423
— releases for self-portraiture, G. Edwards (Pat.), 681
— — D. Friedmann (Pat.), 699
(See also *Focal-plane Shutters*.)
Side-lines for professional photographers. By E. M. Spiers, 153
Sight, photographers' preserving, 115
Silvering mirrors. By J. Graham, 155
— — By W. W. Walli, 370
— — Lundin method, 134
Silverline sketch portraits, D. Charles (Rev.), 194
Sink, dark-room, grid for (Cor.), 179
Slitter, managing the. By Practicus, 23
Sizes, plate, small, new standards, 214, 220, 230, 255, 270, 375
Sketch Photo Co., voluntary liquidation, 713
Sketch portraits, defects in, 182
— importance of whole pose, 10
Soda v. potash (Cor.), 19, 31
Soft-focus commercial photographs, 431
— lens, Cooke f/6.5 (Cor.), 510
Solutions, photographic, preparing. By J. f. Crabtree, 365, 379, 393, 410
Somerset Postal Photographic Society, presentation to secretary, 626
South Africa and assistants (Cor.), 343
Spreight garden party, 403
Specialisation and efficiency, 144
Specimens, bought, ethics and policy, 438, 542
Spectrum lines, photographic measurement of intensity, 533
Spotting prints. By S. H. Avery, 694
Spots on negatives, causes and prevention, 583
Squeegee board, non-slip, 586
Stains for frames, formulae (Soc.), 753
Stains on negatives, removing, 65
Stencils for photo-engraving, 476
Stereoscopy in science and industry, 22
Stereoscope, a simple form (Cor.), 446
Stereoscopic photography, aerial, D. A. English (Pat.), 535
— — causes of disfavour, 290

Stereoscopic photography, giant vision, 373
— — portraiture, 346
— — practical methods, 307
— — scientific applications, 407
— — separation for large negatives (Cor.), 358
— — separation when photographing small objects at close range. By Charles E. Benham, 725, 745, 753
Stereoscopic Society, new American branch, 670
Storing negatives. By Practicus, 489
— sensitive papers, 590
Strip printing, uniform depth in, 15
— — frame, G. S. Moore (Rev.), 608
Stripping solutions for wet-collodion, 492
Studio accessories and furniture. By Practicus, 83
— blinds and curtains. By Practicus, 530
— camera and lens, choosing, 11
— — camera, handling. By Practicus, 215
— — decoration, effect of aspect, 345
— — equipment, buying, 10
— — glazing, advantages of rolled glass, 182
— — handling. By Practicus, 215
— — portable. By Practicus, 186
— — postcard arrangement and apparatus, 125
— — surroundings and aspect. By Practicus, 65
Submarine photographic effects, F. D. Williams (Pat.), 700
— — photography, salvage of Laeurentic, 579
Sulphide toning, failures and causes, 563
— — preliminary sulphide bath, 338
— — re-toning solution, Tonitol (Rev.), 723
— — with barium sulphide, a warning (Cor.), 655
— — with polysulphide, 551
— — v. hypo-alum toning (Cor.), 579
(See also *Hypo-alum Toning*, *Liver of Sulphur*.)
Summer-time, end of, 568
Surplus negative, copyright in, 230
Survey, photographic, of London in 1919, 109, 114
Switzerland, need of British photographic goods. By E. J. Gilmart, 283
— success of British plates. By E. G. Gilmart, 756

T

Tank development for time saving, 679, 702, 716
— — reversal (Cor.), 270, 287, 302, 327
Tanks, developing, J. P. Hensen (Pat.), 565
— — for film spools, vitrified clay, 741
Telephoto lenses for professional work. By Practicus, 647
— — H. Lee and others (Pat.), 591.
Tests for plates, a suggestion to the R.P.S. (Cor.), 447
Textile industry, photographs to replace samples, 635
Thermostat for development experiments, 27
Thornton-Pickard cameras for aerial photography. By S. L. Hughes, 293
Tile work, photographing, 576, 620
Times photographure supplement to weekly edition, 446
Tints, laying, in process work, 491
Tipp, A. W., resumes civilian duties, 249
Titles in view negatives, 258, 735
— — stripping plates for (Cor.), 627.
— — transferring, 574
Tone and lighting in portrait photography, 424
— — values in portraiture, 266
Tonitol, re-toning solution for sepia prints (Rev.), 723
Town-planning and aero-photography (Cor.), 18
Trade marks in China. By W. B. Kennett, 664
TRADE NAMES AND MARKS (See **NAMES AND MARKS**, **TRADE**.)
Traill Taylor lecture, twenty-second. By Rev. A. L. Cortie, 625
Transfer bromide paper, Kerotype demonstration, 16, 127, 254
— — (Pat.), 401
Trimmers, print, J. Merrett and another (Pat.), 252
— — for large prints, 683
Tripod stands, J. Ashford (Pat.), 476.
True-to-nature photographs. By H. Collingridge, B.Sc., 249
True-to-scale process, formula, 550
— — F. Dorel (Pat.), 536
Type-setting, replaced by typewriting and photo-mechanical reproduction, 691

V

Varnish, cheap, for negatives and prints (Cor.), 670
Ventilating and heating the studio, 111
Vertical photography of small articles, 338
Vest-pocket camera, advantages in commercial work, 390
— — for indoor groups, 466
— — specifications for. By E. L. C. Morse, 234
— — Kodak carrying case, Tiranty (Rev.), 683
— — plate-adaptor, Tiranty (Rev.), 683
— — negatives, development for enlarging, 154
— — plates, cutting from larger. By V. Jobling, 564
View postcards, local. By C. Brangwin Barnes, 395
Vignettes, multiple, with print-out papers. By E. A. S., 468
Vignetting for daylight printing papers. By E. A. S., 648
Vision filters for orthochromatic photography, Ilford, 474

W

Ward, Snowden, memorial fund (Cor.), 79
Warming the dark-room, extemporized oil heater, 613
Washer, print, Dependence rotating, Oldfield (Rev.), 326
— — — (Pat.), 652
— — — home-made rotary, 742
— — — P. H. Waddell (Pat.), 103
Washing and fixing negatives, general principles, 630
— — and fixing of prints. By G. F. Stine, 205
— — prints fitting for sink (Cor.), 78
Water, purifying for solutions, 410
Waterproofing wood, anti-sulphuric paint, 552
Ways, the two, of portrait photography, 274
Wedding groups. By Practicus, 577
Weights and measures, metric, in preparing photographic solutions, 365
Wet collodion developer, substitute for acetic acid (Cor.), 226
— — — negatives, saving, 252
— — — stripping solutions, 492
— — — use in photo-engraving, 370
White, Clarence H., interview with, on progress of pictorial photography, 72
Wiggins, Teape Company, manufacturers of photographic raw paper base, 160
Window-dressing, live animals, 718
Winter, outdoor work, 653
Wireless telegraphy, photographic receiver, 287
Women and photography, 206
Wood, imitation of, on metal, 385
— — photographic printing on, for engraving (Anal.) 372
— — By E. L. Turner, 460
Working-up, aids to. By Thermit, 691
Workshops, photographing. By Practicus, 456

X

X-ray directors, G. G. Campion (Pat.), 162
— — fluorescent screens, characteristics. By M. D. Hodgson, 191
— — in industry, 226
— — negatives, half-tone blocks of, 323
— — paper, E. E. Burnett (Pat.), 417
— — with opaque coating, G. W. K. and T. P. K. Crosland (Pat.), 208
— — photographs at the R.P.S., 633
— — definition. By A. Lumière, 183
— — plates, sensitiveness of, measurements, 250
— — — speed of, recent progress, 13

Y

Yellow dye, new, and light-filters made from it. By C. E. K. Mees and H. T. Clarke, 43

Z

Zeiss factory acquired by British optical firms, 190
Zeppelin raids, *British Journal* offices in, 1

AUTHORS' INDEX.

ALDIS, BROS.—
Development of British lenses for aircraft photography, 264
APPLETON, W. B.—
Development of British lenses for aircraft photography, 243
ARDASEER, G.—
Focusing screen for photo-micrography, 363
Photo-micrography without a microscope, 483
AVERY, S. H.—
Spotting prints, 694
B. (C. E.) (Benham, Charles E.)—
Stereoscopic photography, 290, 307, 340, 378, 406, 725

NOTE TO SUBSCRIBERS WHO BIND THE "COLOUR PHOTOGRAPHY" SUPPLEMENT SEPARATELY.

Owing to exigencies of "make-up" it has not been possible to include in this index sheet a title page for the 1919 volume of the "Colour Photography" Supplement. For the convenience of those who bind the "Colour Photography" Supplement separately the publishers have had printed a few title pages, with index, of the Supplement, and will be pleased to send one of these sheets on application.

COLOUR PHOTOGRAPHY.

VOL. XIII.—1919.

INDEX.

The following abbreviations are used in the Index to indicate the nature of the subject matter:—

(Pat.) Patent.

(Dec. Pract.) Decennia Practica.

- Apparatus for colour photography, essentials. By R. M. Fanstone, 41
- Autochrome photography, effect of the light-filter. By B. E. Havelock, 22
- plates, simplified developing. By A. and L. Lumière and A. Seyewitz, 37
- Autochromes by artificial light. By C. J. Belden — for lantern-slides. By R. M. Fanstone, 45
- Books on colour photography, 24
- Bromoil, three-colour, enlargements from Joly type negatives. By S. H. Williams, 15, 18
- Butler three-colour camera, registration (Cor.), 36
- Carbon tissue for multi-colour prints (Dec. Pract.), 12
- Cellulose ester cum colloid two-colour screen films, 46
- Cheron prismatic dispersion process (Dec. Pract.), 20
- Christensen's patent, three-colour sensitive units, 43
- Cinematography, six-colour, J. Shaw (Pat.), 26, 29
- two-colour, Douglass, 5
- — Hamburger (Pat.), 13, 17
- Colour photography, where we stand, 21
- transparencies from colour-sensation negatives, F. E. Ives (Pat.), 9
- Colour-sensitising dyes, preparation of. By L. E. Wise, E. Q. Adams, J. K. Stewart, and C. H. Lund, 34
- Composite colour process, Hess-Ives patent, 5
- Copper and iron toning for two-colour prints or films, F. E. Ives (Pat.), 38
- Diffraction process (Wood) of colour photography (Dec. Pract.), 7
- Douglass two-colour cinematography, 2
- Drac system of direct colour photography (Dec. Pract.), 7
- Dye-image colour process, Christensen patent, 48
- mordant process, new photographic. By F. E. Ives, 1
- Gorsky, Prokudin, colour process, 48
- Hamburger two-colour cinematography, 13, 17
- Hess-Ives composite mosaic and full-tone colour process, 5
- Imbibition screen-plate colour process, Pedersen patent, 8
- Iron and copper toning for two-colour prints or films, F. E. Ives (Pat.), 38
- Ives, F. E., composite mosaic and full-tone colour process, 5
- Lantern-slides by screen-plate processes. By R. M. Fanstone, 45
- Light-filter in Autochrome photography. By B. E. Havelock, 22
- Lippmann process of direct colour photography (Dec. Pract.), 3
- Mars-star pseudo-colour process (Dec. Pract.), 4
- Paget colour process, excluding dust from the plate, 12
- — care of screens and filters, 14
- Paget colour process for lantern-slide making. By R. M. Fanstone, 45
- — making the transparency, 24
- — transparencies, registering, 44
- Pedersen, H., imbibition screen-plate colour process, 8
- Pinaverdol and pinacyanol, preparation of. By L. E. Wise, E. Q. Adams, J. K. Stewart, and C. H. Lund, 34
- Prismatic dispersion for photography in colours (Dec. Pract.), 12, 20, 27
- Prizma colour cinematography, a correction, 20
- Prokudin-Gorsky colour process, 44
- Pseudo-colour processes (Dec. Pract.), 4, 11
- Review of colour photography. By H. E. Rendall, 31, 33
- Screen-plate, colour, exposure hints, 40
- Shaw six-colour cinematography patent, 26, 29
- Smith (J. T.), patent cellulose ester cum colloid two-colour screen films, 46
- Solgram colour prints (Dec. Pract.), 4
- Three-colour, a blind alley? (Cor.), 36, 39, 44
- sensitive units for colour photography, J. H. Christensen's patent, 43
- Transparency viewing apparatus and retouching stand combined, 23
- Two-colour prints or films by copper and iron toning, F. E. Ives (Pat.), 38
- screen films, J. T. Smith (Pat.), 46
- Wood diffraction process (Dec. Pract.), 12

AUTHORS' INDEX.

- ADAMS, E. Q., WISE, E. L., STEWART, J. K., and LUND, C. H.—
Laboratory preparation of the colour-sensitising dyes, pinaverdol and pinacyanol, 34
- BELDEN, C. J.—
Autochrome photography by artificial light, 25
- FANSTONE, R. M.—
Essential features in apparatus for colour photography, 41
Lantern-slides by the screen-plate process, 45
- HAVELOCK, B. E.—
Light-filter in Autochrome photography, 22
- IVES, F. E.—
New photographic mordant dye process, 1
- LUMIERE, A. and L., and SEYEWITZ, A.—
Simplified method of developing Autochrome plates, 37
- LUND, C. H., WISE, E. L., ADAMS, E. Q., and STEWART, J. K.—
Laboratory preparation of the colour-sensitising dyes, pinaverdol and pinacyanol, 34
- RENDALL, H. E.—
Review of colour photography, 31, 33
- SEYEWITZ, A., and LUMIERE, A. and L.—
Simplified method of developing Autochrome plates, 37
- STEWART, J. K., WISE, E. L., ADAMS, E. Q., and LUND, C. H.—
Laboratory preparation of the colour-sensitising dyes, pinaverdol and pinacyanol, 34
- WILLIAMS, S. H.—
Three-colour Bromoil enlargements from negatives of the Joly type, 15
- WISE, E. L., ADAMS, E. Q., STEWART, J. K., and LUND, C. H.—
Laboratory preparation of the colour-sensitising dyes, pinaverdol and pinacyanol, 34

APPENDIX.

The following Supplementary Index includes the entries referring to articles, etc., on colour photography which have appeared in the "British Journal of Photography" during 1919.

- Colour cinematography (Pat.), 16, 386
- digest of recent processes, 27
- photography and cinematography (Gorsky and Rodgers and Finnigan), 537
- composite mosaic and full-tone process, Hess Ives Corporation (Pat.), 61
- copper and iron toning, Hess-Ives Corporation (Pat.), 578
- mosaic imbibition process, H. Pedersen (Pat.), 61
- screenplate, Dufay, 606

The Summary of contents which usually occupies the lower half of this column will be found at the foot of the page overleaf and will continue to be placed there whilst its regular position is required for notices relating to the forthcoming "H.J. Almanac."

The Indexed Almanac.

WE may, perhaps, be excused for thinking of the Almanac as one of the best indexed of photographic manuals. But we endeavour to make the index a fitting counterpart of the very many and varied items of information which are contained in the Almanac. Indexing, as anybody knows who has done any of it, is work which calls for patience and discretion in about equal measure. The discretion consists in choosing the entries in the index which are likely to be looked for by a reader who obviously knows nothing of the indexer's method. From that point of view we hope that the reader will find the index to the forthcoming Almanac a speedy and reliable means in seeking any item, however small, in its many pages. It is not until we come to compile the index to the Almanac that we realise the immense amount of practical information which it contains. The index is therefore contrived so that it may fulfil its proper function of pointing to every piece of contents, and of doing this no matter from what point of view the seeker regards a particular subject. For example, the process of making line drawings from bromide prints is indexed both under "Bromides" and under "Line," and the same applies to scores of other items.

The index this year is further reinforced by the inclusion of the many words, terms, and expressions commonly used in photography which are the subject of the article "Photographic Definitions," in which their meaning and practical significance are briefly explained. The article thus supplies a readable and not unduly disjointed survey of practical photographic methods, whilst the index supplies the means for the beginner to ascertain the meaning of any particular word or term which he may seek.

And in this reference let it not be omitted that the goods advertised in the Almanac are also the subject of a separate index, from which is seen the makers or dealers supplying any given article together with the page of the Almanac on which their advertisement appears.

EX CATHEDRA.

A Hand Camera Pioneer.

In a recent article by Mr. Ward Muir in which he pays tribute to the memory of the "old master" of camera-making, George Hare, he asserts that the conservative nature of that gentleman led him to avoid the construction of hand-cameras. This is hardly correct as Mr. Hare made many of the earlier box-form hand-cameras, most of which were to the order of Mr. Dallmeyer. We believe also that he was the originator of the type of camera in which the front board folds up and encloses the lens and shutter, as in the Una and Alpha of to-day, or we might even say the folding Kodaks. This early instrument was called the "box-form camera," and was fitted with a rapid rectilinear lens in the usual mounting with a T.P. shutter fixed upon the hood, which made it rather bulky. The bellows had double extension and were made wide at the front so that a pair of stereo-lenses could easily be accommodated. We believe only a few of these cameras were made as they were for half-plates only, and the early hand-cameras were nearly all for quarter-plates. Mr. Hare's cameras were noted not only for their beautiful workmanship, but for the studied simplicity of design, no fitting being added unless it were really useful.

The Patent Office Library.

A new facility has just been added to the library of the Patent Office, Southampton Buildings, London, W.C.2. It is now possible to obtain a photographic copy of any document in the library, such as the page of a book or periodical. A photographic department for this purpose has been set up in a room adjoining the library. It is fitted with a Photostat machine with which either negative or positive copies are supplied, according to an official tariff. The provision thus makes it possible for any member of the public to obtain accurate reproductions of passages or pages in books which are out of print, and presumably such official copies will be accepted in courts of law as equivalent to the production of the original volumes. In making this reference to the further service being rendered by the Patent Office Library, it may be mentioned for the benefit of those who do not know the library that its collection of technical books is probably the finest in the country, whilst the freedom with which the shelves may be consulted makes it unique among public institutions. It includes an exceedingly comprehensive set of photographic books and periodicals.

German Bombs.

With the publication of the official report on the air raids on London it is now permissible for us to refer to the incident of October 13, 1915, when two bombs from an enemy airship

fell, one immediately to the rear of the "British Journal" offices and the other in the middle of the roadway nearly opposite their frontage. The force of the latter naturally shattered and blew in all the windows and did some other minor damage, but fortunately no life was lost. It was late in the evening, the "B.J." for the week had, in newspaper language, "been put to bed," the staff had gone home, and the caretaker and his wife, who, by a piece of luck, were in the rear portion of the building, suffered only the mental shock of the two successive explosions from the effects of which they have still not completely recovered. In a later aeroplane night raid, in which part of Covent Garden Market suffered, some slight damage was again done to the "B.J." offices. The souvenirs in the shape of twisted metal and splintered wood, which have been preserved from these assaults, are not necessary to keep in our minds the sense of loathing for the nation by whom these acts of murder were planned. We do not disguise from ourselves that they were kindness in comparison with scores of others committed according to plan during the course of the war. But, naturally, their effect upon ourselves as eye-witnesses was disproportionately great. At any rate their occurrence and the recollection of what others have suffered in similar raids will confirm us in our policy of having nothing to do with advertisements of German goods.

Red Tones on P.O.P.

A pleasing relief from the sepia and black tones which now dominate the showcase may be obtained by using matt P.O.P. toned to a red tint. The colour, while not actually that of a red carbon, is quite distinct from the brown and purple tones usually obtained by gold toning. The process used is quite simple and differs in no way from the separate toning and fixing with which we are all familiar; in fact by prolonging the toning very pleasing browns may be obtained. Glossy paper may be used, but is not as a rule so satisfactory as the matt variety. The phosphate toning bath is recommended, and is made as follows: Phosphate of soda, 30 grains; water, 10 ozs.; chloride of gold, 1 grain. The prints are washed as usual until the milkiness quite disappears: four changes of water with five minutes immersion in each are usually sufficient. They are then transferred to the toning solution, only one print being toned at a time. It is a good plan to take one print and lay it in a dish of clean water by the toning bath, while the toning is done, to serve as a guide. As soon as the print in the toning solution shows a distinct change it is

put straight into the hypo bath, which should not be stronger than two ounces to the pint, and another print-toned. The toning only takes a few seconds, and it is impossible to obtain even tones if a number are toned at once. Although there is so small a quantity of gold deposited, the prints stand very well, some now over fifteen years old having shown very little deterioration. It may be well to note that the toning solution should be made one hour before using, and that it should then be used up, as it does not keep more than a few hours.

BRITISH AND GERMAN LENSES.

WITH the prospect of the photographic industry reverting from its war preoccupations, it is natural that interest should be taken in the progress of those branches of it which previously were in keen competition with German makers. Of these that of lenses presents itself in the first place, and we are glad to see that the question is being energetically discussed in our contemporary, "The Photographic Dealer," where Mr. James A. Sinclair has called for a candid examination of the matter from several points of view. His letter has quickly elicited some interesting opinions, chief among which perhaps is the statement of Mr. Oglesby (of Messrs. Sands Hunter, and therefore in a position to test the pulse of the lens-buying public), to the effect that purchasers of second-hand lenses at the present time are prepared to pay a premium of 50 per cent on the list price for German anastigmats of repute, whereas British instruments of similar rank barely command the list price. The experience is one which is in accordance with the general preference among photographers, and it emphasises the necessity for the energies of those in the lens industry to show that it has its origin in the propaganda industriously carried on by the German makers. Few photographers, and probably still fewer of those engaged in retailing lenses, have adopted Mr. Sinclair's practice of submitting lenses to authoritative tests. They have been content to assume that a German lens was, as a matter of course, superior to a British one, and, given that initial bias, it is perfectly natural that in such qualitative work as photography the actual optical performance goes undiscovered even when, which is rarely the case, comparative camera tests are undertaken.

But to-day we are in a position to destroy this tradition. The war, in which optical definition of aerial photographs has been a vital factor, has, so to speak, enlisted British and German opticians in a trial of strength; a trial, how-

SUMMARY.

The first of a short series of articles by "Practicus" deals with the elements of lighting in portraiture. Simple directions are given for arranging the blinds, the abuse of the reflector, and other matters. (P. 3.)

Now that hostilities are suspended, we are getting some idea of the marvellous developments in lens manufacture which have occurred during the war. British lenses have decisively beaten the German product, and we hope that we shall hear no more about the "superiority" of the latter. (P. 2.)

The "B.J." offices came in for their share of damage from enemy air-raids. D.O.R.A. now permits us to give some account of the happenings on page 2.

A simple method of obtaining red-toned prints on matt P.O.P., using the ordinary materials, is given on page 2.

An important innovation has been made at the Patent Office Library, it being now possible to have documents, drawings, or pages of books reproduced by the Photostat. Details of the procedure will be found on page 1.

A note on the late Mr. George Hare's part in the evolution of the hand-camera finds place on page 1.

Under the heading of "Patent News" will be found specifications of an automatic light switch for plan-copying machines and dye-toned images. (P. 5.)

An easy method of converting formulæ expressed in terms of the metric system into apothecaries' weight is given under "Assistants' Notes on page 5.

A very successful exhibition of British scientific products is being held at Manchester. We print some descriptions of objects of photographic interest on page 7.

The assistants' question and the problem of halation are the subjects of correspondence on page 7.

Changing bags, flashlight work, and studio lighting are among the subjects dealt with in "Answers to Correspondents." (P. 8.)

The new issue of "Photograms of the Year" is noticed on page 6.

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

Dyed images specially for colour cinematography are much in evidence just now. Mr. F. E. Ives gives full particulars of an improved mordanting process in an article on page 1.

Another dyed-image method, by which alternate cinematograph images are dyed red and green, the one set of pictures being protected by a removable coating of varnish while the other is being dyed, is detailed on page 2.

Decennia Practica is devoted to the Lippman or interference-process of colour photography, an improved method of making the emulsion being described, and to pseudo-colour processes. (P. 4.)

ever, in which the British contestant was handicapped by the fact that in the past he had relied upon his antagonist for the staple and highly finished material for the manufacture of his lenses. With the removal of the restrictions imposed by D.O.R.A., it is permissible to say that in this unequal contest the British optician has proved himself superior. With glass that is wholly of British manufacture he has produced instruments which optically are not merely superior to those of the Germans, but much superior to them. Test photographs which we have seen—tests designed to provide rigid photographic records—emphasise this fact in respect to lenses of different types successively originated by both British and enemy designers as progress in aerial warfare forced the photographic machines higher and higher in the air. And let it be understood that the degrees of optical performance in regard to which these comparisons have been made are very high ones. They represent a much more critical definition than would be ample for ordinary photographic purposes. Some idea of the character of the results will be gathered when it is stated that in aerial photographs taken with these all-British lenses at the height of 15,000 ft. it has been possible to note the presence of barbed wire. It is in this domain of high performance that the British lenses have beaten the German. We would go as far as to think that the superiority of the British aerial photographs has been a material factor in the defeat of the enemy, and we want the fact to be remembered if and when we should hear anybody again taking it for granted that in optical matters the Germans are unsurpassed. It amounts to this. There has been a competition in which the prize was the most colossal the world has known for a specific optical result. The German has come out second, though circumstances were immensely in his favour. Capt. Hetherington, in the "Photographic Dealer," has told us as much as this, and as the officer responsible for the supply of lenses to the Air Force no one is in a better position to know than he. A more detailed and technical account will, we hope, be published; it is a duty which the Air Board owes to opticians who have served it.

It follows from what has been said that we may expect the British lens manufacturers to lose no opportunity which is open to them to maintain, spread, and develop the reputation which their instruments should rightly enjoy here and abroad. We do not care particularly what means they employ, but whatever they are, they should plainly be employed more abundantly than in the past. The suggestion has been made that makers of lenses should collectively emphasise the merits of British lenses. The suggestion may be of value if the effort is made in supplement to others—an extra item in a total of propaganda

But we are disposed to think that the form rather than the mode of bringing British lenses before the photographic public is the matter which calls for an imaginative and constructive policy. Lenses are bought largely by people who value them very properly, purely in accordance with the results they will produce. Most purchasers of them don't care twopence about their optical principles. Without knowing anything else about a lens they will buy it because, for example, the maker exhibits photographs taken with it on an expedition in Patagonia, inferring that the explorer would choose the best lens he could get. The appeal by result was in the past employed about as liberally by the Germans as it was neglected by the British opticians. Let our lens makers realise that the tests by which they value their instruments mean no more to the average user than the chemical analysis of a sample of cocoa does the housewife. The cocoa maker is a notable user of pictorial advertisement; the lens maker, on account of the direct relation between the picture and the article to be sold, has much better reason to pursue this method, which, of course, is not the only one that may be adopted.

In whatever propagandist programme may be evolved, the dealer must necessarily take a part. As the person who comes immediately in touch with purchasers, he can assist as no one else can. A leading dealer has recently referred to the assistance given to dealers through the advertising by the German makers, and has mentioned the more favourable terms on which German lenses were retailed. It is a purely commercial view, a view which any business man quite properly takes, but nevertheless we are prepared to say a view which can be too exclusively taken. In the selling of comparatively costly articles, such as a highly priced lens, the customer of a dealer rightly expects to benefit in his purchase from the knowledge of the goods which the dealer (presumably) possesses. It is perhaps a rather altruistic aspiration, but is it too much to expect that a dealer will pay a measure of regard to this part of his function? In the interests of British lenses, which for the present at any rate are his interests, it is hoped that it is not too much. But whatever may be the degree to which the uncommercial element may enter into the dealers' transactions, there is now the occasion for the dealer to add the weight of his influence on the side of British lenses in the direct and personal way which is possible to him. How many dealers, we wonder, have sent a lens to the National Physical Laboratory for their own information? How many have done more than display showcards and printed matter? We should like to see dealers take up a more discriminating rôle in their supply of lenses, and we are sure that is what lens-makers in this country would like them to do.

PRACTICUS IN THE STUDIO.

A TALK ABOUT LIGHTING.

LIGHTING the sitter is one of the most difficult subjects to discourse upon that could well be chosen, for so narrow is the margin between success and failure that it is not possible to give definite rules which will ensure the same results under different conditions; in fact, so far as this is true that there is a legend that one successful portraitist abstains from having his windows cleaned lest the lighting should thereby be rendered too hard.

Nearly every competent writer on the subject has recommended the study of lighting to be begun with a plaster bust, and with this I heartily agree. The only thing better would

be to follow the example of Adam Salomon and have life-sized wax figures with hair and clothes complete. A life-sized bust is not an expensive luxury even in war-time, for I recently purchased one near Hatton Garden for five shillings. It was the head and shoulders of Gibson's Venus, and has not special pretensions to classical beauty; it is just a moderately good-looking young woman with her head well balanced upon her shoulders. Busts having the head in unusual positions should be avoided, as the lighting which might suit them will not be useful for sitters.

Having got our bust, the first thing to be done is to give

it a coat of buff or very pale terra-cotta distemper, so that the light values will be about the same as those of the living model. This is very important, as white plaster reflects far too much light for our purpose. The reason why I advocate the use of a bust instead of a living sitter is that the latter cannot keep still for the time required for study, and the student will quickly see how a slight movement of the head upsets all his plans for obtaining a certain effect.

The bust must be placed on a table so as to be about the height of an ordinary sitting figure, and in front of a plain medium-toned background. It should be in such a position that a high side light falls upon it, the light being rather to the front of the object. In an ordinary span-roof studio this would mean that the dark blinds or curtains would be drawn over one end of the studio, both top and side, for about five feet. The bust should be about three and a half feet from the end wall, the next blind should be half-down and the next quite open; the side light is obscured up to nearly five feet from the ground, and is open for about six feet run. If we now examine the lighting we shall find it fairly round, but rather contrasty. This is all for the best, for we can readily see the effect of altering the positions of the bust, the blinds and the camera respectively. One golden rule, by whom originally written I know not, is that "light from the sitter's end of the studio gives contrast, while light from the camera end gives softness." I cannot too strongly impress this fact upon the beginner. In ordinary circumstances, if the lighting is too harsh, open more blinds over the camera end; if too soft, close them over the camera and open them near the sitter. This one rule is the key to simple lighting, and its application will prevent much floundering in the early stages. If we do not want to alter the blinds we may move the sitter; if she goes further under the dark blinds we get softness; if she comes forward we get contrast.

Excess of top-light is the commonest fault in portrait lighting; but there are times when top-light is needed. A flat face with insignificant features calls for it, as Mr. H. P. Robinson says: "I think I should use a good deal of vertical light in taking the portrait of a Chinaman." If the sitter had strong features and deep-set eyes such a lighting would be disastrous. We may now try the effect first of turning the bust to and from the light, and you will quickly see how the modelling of the face is affected. As we turn the nose to the light the further cheek becomes illuminated, while as we turn it away it sinks into shadow. I would ask you to remember that neither the camera nor the sitter is screwed to the floor, so that you can obtain the same position of the head, but with very different lightings, by turning it till the desired effect is obtained, and then placing the camera in the position whence you observed it. Always keep your eyes open for accidental effects of lighting, and note the sitter's position in the studio for future use; some of these "observed" lightings are much better than those carefully arranged. I have nearly always found that the effects obtained with dark blinds and clear glass only are rather too vigorous for the ordinary run of work, hence it is very desirable to have in addition very thin white blinds or curtains so as to diffuse the light a little and tone down the glaring effect of the high-lights. If there are no white blinds an ordinary circular head-screen covered with thin nainsook or pale-blue nun's veiling is very useful. The nearer this is placed to the sitter the softer will be the lighting, and vice versa. In studios which are so placed that direct sunlight falls upon the glass during any period of the day white blinds should be used to cover all the glass. I have worked in this way in a studio facing due west, on which the sun shone from 11 a.m. until evening. In such a studio we must not have too large an expanse of white-covered window open at once, or we shall get flat negatives.

A point which should never be lost sight of is that the actual design or pattern of the studio is of no moment. So

long as the light can be made to fall upon the sitter at the desired angle, ridge roof, single slant, top-light, high side-light will all give the same result if properly handled. Much more depends upon outside influences; trees, walls, other buildings all serve to modify the lighting, and an arrangement of blinds which will suit the sitter in one studio may fail to do so in another which is differently placed.

A lofty studio is not to be desired. I remember one clever photographer who said that he would work under a cucumber-frame if he could. In a high-roofed studio the light is very difficult to control, as it is too far away from the sitter. Even, soft effects are easily obtained, but when any decided lighting is needed it becomes necessary to close all the blinds and to use the side-light only, and that only in a limited area.

A few words on unusual forms of studio may not come amiss. When working in a studio which has top-light only, the sitter must be placed well back under the dark blinds, and plenty of light admitted from the "camera end." It is also often advantageous to turn the sitter slightly to one side of the studio and to work the camera close to that side of the studio towards which he is looking, the background being, of course, placed diagonally across the corner. In a studio with a high side window only it is often necessary to place the sitter as close to the window side as possible, so as to get the effect of top-light. If too low a side-light be used the eyes are filled with light and look flat. What is sometimes called a "miniature-painter's light" is a high front light. This gives a very even illumination of the face, but if properly managed there should be sufficient shadow on one side to avoid flatness. If it be desired to copy the lighting in an existing photograph or even a painting, if by a good artist, the spark of light in the eye forms a reliable guide as to the position of the dominant light. If this be high or nearly in the centre of the top of the iris, in the position say of 11 o'clock on a watch dial, it denotes a high front light, if in the position of 9 o'clock a low side light, and so on. In some fancy lightings it may even be at 6 o'clock, which shows that the light comes from below.

I will now deal briefly with screens and reflectors. The head-screen I have already dealt with as far as lighting the features is concerned, but it has other uses, such as subduing the light on white drapery. Nothing is more objectionable than to have a white dress brilliantly illuminated, making the face appear too dark and receding into the background. By use of the small head-screen this may be avoided, the shadow being cast where required. In some cases a screen covered with a thin open black material is useful, as it will cast a shadow without diffusing white light in other directions. Reflectors are usually relied upon too much; only when the lighting is nearly satisfactory but the shadows are too dark should they be introduced, and then not placed close up to the sitter. In this position they destroy all the modelling on the shadow side and give an unnatural appearance. It is unfortunately too common for the operator to make a hard lighting and then to use the reflector to even up the face. This is wrong, as it does nothing to subdue the overlighting on the other side. There is no need to be afraid of using a screen or white blind to soften the high-lights, as it does not cut off any light from the shadows which are still receiving front light and reflected light from the studio. If the same exposure be given with the high-lights screened the negative can be developed for the shadows without the high-lights blocking up.

In conclusion, I would caution the tyro against judging lighting by the eye alone, the negative being the only test. The plate does not always see the sitter in the same way as the operator does. Some plates have a tendency to intensify the light, while others soften it. The lens also has a say in the matter, a short-focus lens usually giving a more brilliant negative than a long focus one does. This is partly due to scattered light in the studio, but it also seems to be caused by the distance between lens and plate. Naturally the operator will see

that his lens is clean, his camera well blacked inside, and his dark-room light beyond suspicion before he starts work, or he is simply inviting failure in any attempt to secure good lighting.
PRACTICUS.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Easy Conversion of Metric Formulæ.

ALTHOUGH the metric system of weights and measures has many advocates in the world of photography, it cannot be said that the average photographer or his assistant takes kindly to it, and many no doubt feel a little annoyed when a formulæ is given in gms. and c.c.s. with no accompanying equivalents, or at any rate quantities, in the more familiar English system of grains and ounces.

Several methods of conversion have been advocated, and all may be simple enough to expert mathematicians or those assistants who have time to get used to them, but the simplest plan, and one needing but little skill in arithmetic, is the following, when, as is usually the case, the constituents of a formula are given as so many gms. per litre (1,000 c.c.s.).

The plan is to reckon the 1,000 c.c.s. as 16 ozs. and multiply all the gm. quantities by 7, which plan will give the number of grains per 16 ozs. of solution, there being no real reason why the 1,000 c.c.s. should be reckoned as a pint of 20 ozs., as many appear to imagine, for as a matter of fact a litre is 35 ozs. and 94 minims.

As an illustration of this "rule of seven" plan the one-solution scalol-hydroquinone developer may be taken :

Water	1,000 c.c.s.	= 16 ozs.
Soda sulphite crystals	50 gm. x 7	= 350 grs.
Scalol	2.5 gm. x 7	= 17½ grs.
Hydroquinone	4.5 gm. x 7	= 31½ grs.
Soda carbonate crystals	75 gm. x 7	= 525 grs.
Pot. bromide5 gm. x 7	= 3½ grs.

Sixteen, eight, or four ounces are quite as convenient as the more popular twenty, ten, and five ounce quantities. If, however, the worker prefers the 20 ozs. lots to the 16 ozs. given by the above system, the multiplying by seven can still be carried out, and when the figures are obtained they are simply divided by four, which gives, of course, the 4 oz. quantities, they being then multiplied by five to produce the quantities per Imperial pint—L. T. W.

Exhibitions.

WALTER BENINGTON'S PICTURES AT HAMPSHIRE HOUSE.

THE third of the season's "one man exhibitions" has now been inaugurated at Hampshire House, and the artist-author of the works on view is Walter Benington. This well-known photographer first won his spurs in the ranks of the amateurs, but soon he enlisted under the banner of professionalism, and speedily took that rank among the practitioners of the art to which his taste, technique, and versatility so fully entitle him. Though in recent years his work has more generally been shown at the Salon, in earlier days his pictures were to be seen at the Royal, and many other of the best galleries.

There are no fewer than sixty-four pictures at Hampshire House—enough to give visitors and students a fairly comprehensive idea of his aims and the media and methods by which he produces them. The show, which is open every day—excepting between 1 and 2 p.m.—is well worth a visit.

FORTHCOMING EXHIBITIONS

February 20 to 22.—Leicester and Leicestershire Photographic Society. Secretary, H. C. Cross, 80, Harrow Road, Leicester.
February 22 to March 8.—Edinburgh Photographic Society. Secretary, George Maasie, 10, Hart Street, Edinburgh.

A conversation of the staff of Mr. F. A. Swaine, Southsea, was held on Friday, December 20, and was attended by nearly 100 persons. A most enjoyable evening was spent.

Patent News.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

PLAN-COPYING MACHINES.—No. 120,620 (Nov. 14, 1917).—The invention consists in a mechanical device adapted to be applied to practically any type of photo-copying machine for automatically extinguishing the light (and also preferably stopping the machine) at any predetermined point in the exposure of the print.

The device comprises an arrangement of cable, wire, or the like connected at one end to the lamp control switch, and suitably anchored at the other end; the cable carrying adjustable stops adapted to be operated by a part moving in relation to the lamp or the machine.

Figures 1 and 2 show the invention applied to the well-known pattern of stationary printing cylinder, in which Figure 1 is a

Fig. 2.

Fig. 1.

general perspective view of a copying machine of the type in which a movable lamp is lowered into a stationary, copying cylinder, and shows our invention applied thereto.

Figure 2 is a detail view of one part of our automatic control device.

a is the copying cylinder of ordinary construction with movable lamp *b*, winding gear *c* and light switch *d*. The winding gear *c* for the lamp supporting wires *e* and *f* may be operated by hand or motor for raising the lamp into the position illustrated. In the example given the gear *c* has a spring actuated knob *g*, which is drawn out to enable the lamp *b* to be lowered; a suitable braking arrangement on the gear determining the speed.

In applying the invention a wire *h* is attached at one end, preferably through the medium of a tension spring *j*, to a convenient fixed point and is passed downward parallel with and closely adjacent to or between the lamp wires *e* and under a pulley *k* at or near the base of the machine, and the other end of the

wire *h* (which is preferably arranged in close proximity to the lowering gear *c*) is connected to the handle of the lamp switch *d*. The lowering device is provided with a pivoted cranked catch or trigger *l* having a jaw end *m* adapted, whilst the machine is in operation, to engage and hold the spring-controlled knob *g* of the lowering gear in its outer or operative position. Each end of the wire *h* carries an adjustable stop, marked *n*, *o*, respectively, and the arrangement is such that as the lamp approaches the end of its travel as determined by the adjusted positions of the stops, a cross-bar *p* carried by the lamp wires *c* engages with the upper stop *n*, thereby exerting a pull on the wire *h*, which is transmitted to the switch handle and extinguishes the lamp. At the same time the stop *o* at the other end of the wire is drawn into engagement with and serves to release the cranked catch or trigger *l*, whereupon the spring-controlled knob *g* of the lowering gear is immediately returned to its inner position, and the downward movement of the lamp *b* is stopped.

The device can be applied to copying machines with rotating cylinders.—Arthur Sydney Baylis, Bleidheim House, 2, Lowther Street, Coventry; and Bernard William Dawkins, Glencar, Spencer Avenue, Earlsdon, Coventry.

DYE-TONED IMAGES. No. 113,617 (Feb. 20, 1917).—Silver images are bleached in a solution of copper ferricyanide, the copper-toned image acting as a mordant for certain dyes. The details of the specification are given on another page in the "Colour Photography" Supplement.—Hess-Ives Corporation, 1201, Race Street, Philadelphia, and Frederic Eugene Ives, 1327, Spruce St., Philadelphia.

New Books.

Photograms of the Year 1918. Edited by F. J. Mortimer (London: Hiffe and Sons, Ltd. 5s. and 6s. net.)

A SELECTION of the practical work of the year, exhibited and unexhibited, is offered for the twenty-fourth time in the 1918 "Photograms." The volume, which roughly may be taken as a reflection of the exhibitions, marks the predominance of portraiture and figure study and the neglect of landscape which have characterised the work of exhibitors during the last few years. The landscapes in this book which have a quality above the topographical can be counted on the fingers of one hand; portraits and figure studies fill three-quarters of its pages. The prohibition of outdoor photography will be pleaded in excuse, but the movement was well advanced before D.O.R.A. drove our cameras indoors. We could wish that our good friend Mr. W. R. Bland, in his rôle of fatherly and kindly commentator on these "pictures of the year," might urge the claims of landscape. He is evidently not supposed to do anything of the kind in "Photograms," but only to say a few words about each reproduction, but as he has managed this year to squeeze a little chapter on the soft-focus lens into these close-clipped comments, perhaps, with six months to think about it, he can find a way to insinuate the needed object-lesson among his observations of 1919. Among the other literary contents of the book are an expected and an unexpected contribution. Mr. R. Child Bayley writes one of his articles on the Royal Photographic Society, and Lieut.-Col. Moore-Brabazon sketches a new branch of aerial photography—the pictorial. The latter is a disturbing forecast for the critic, who must qualify as an aerial traveller if any weight is to be attached to his judgments.

GOSAMER AND HONEY.—A little volume of poems bearing this title is among the latest publications of Mr. Arthur L. Humphreys, 187, Piccadilly, W. We cannot regard reviews of poetry as coming within our province, but the collection has an interest for us and for many of our readers as the work of Miss Joan E. V. Warburg, the 16 year-old daughter of Mr. J. C. Warburg. Having said this much, it may be permissible to observe that the poems exhibit, many of them, an imagination and sense of rhythm remarkable in one of so few years. They have a delicate air-bell kind of sweetness, and certainly promise gifts of exceptional character.

THE HANDS IN PORTRAITURE.—The latest issue, No. 172, of "The Photo-Miniature" is one which every professional photographer ought to get and study. It is a little treatise by the well-known

New York photographer, Mr. Charles H. Davis, on the art of posing hands in portrait photographs. Mr. Davis is acknowledged as a master in the beautiful drawing of the hands which, with the aid of his own art, he makes the camera produce for him; even if he were not, the thirty-odd reproductions of his work, which form part of his scheme of instruction in this little book, would show him to be one of the comparatively few photographers who have realised the beauty of hands and succeeded in embodying it as an inherent part of a portrait. It would be useless to attempt to epitomise his manual. Suffice it to say that it is written by an artist—but an artist who has had to work under photographic conditions, and realises how advice, conceived in a spirit of pure art, requires to be tempered to others who must submit to the same limitations. And so it is not in the least an exaggeration to say that the little book is worth many times its price to any photographer. At present, so far as we know, it is not obtainable in England, but must be ordered direct from Messrs. Tennant and Ward, 103, Park Avenue, New York, with remittance of 1s. in British postage stamps or international coupons.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, JANUARY 4.

Rodley and District Photographic Society. Social Evening.

MONDAY, JANUARY 6.

Bradford Photographic Society. "A Chat on Pictorial Portraiture," with numerous illustrations. Mr. and Mrs. F. Toulson.
City of London and Cripplegate Photographic Society. "Straight versus Controlled Photography." R. H. Lawton.
Dewabury Photographic Society. Annual General Meeting.

TUESDAY, JANUARY 7.

Hackney Photographic Society. Opening of "One Man" Exhibition.

WEDNESDAY, JANUARY 8.

Croydon Camera Club. "The Early Chapters of Photographic History." A. Mackie.
Edinburgh Photographic Society. "How to Make Enlargements." J. A. Angus.
Halifax Scientific Society (Photographic Section). Lantern Lecture at Harrison Road.
Dennistoun Amateur Photographic Association. "Photographic Economy." C. Rothead.

THURSDAY, JANUARY 9.

Brighouse Photographic Society. "Blus Print Process." H. P. Metcalfe.
Huddersfield Naturalist and Photographic Society. Exhibition of "Photography and Poems" Prize Slides.
Hammersmith (Hampshire House) Photographic Society. "Camera Records from the Zoological Gardens." D. Seth-Smith, F.Z.S.
Rodley and District Photographic Society. Members' Night.
Liverpool Amateur Photographic Association. Slides of R.P.S. and Lancashire Photographic Union.

FRIDAY, JANUARY 10.

Dennistoun Amateur Photographic Association. "Enlarging." R. Wallace.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the Council was held on Friday, December 13. Present:—Messrs. M. Adams, Gordon Chase, A. Corbett, W. E. Gray, R. Haines, A. Mackie, Lang Sims, H. A. St. George, and F. G. Wakefield.

The hon. secretary referred to his efforts in finding out how the association could assist members to secure early release from Army service.

A letter was read from a member asking for advice in reference to an agreement with a pupil not to open business or take a situation with a photographer within a certain radius of his studio. The reply was that the law only allowed such restriction as was necessary to protect the business, and to what extent that restriction might be carried depended on the circumstances of the case.

The circumstances were related by the hon. secretary of an interesting inquiry involving the ownership of the copyright in a photograph taken by a photographer, at the suggestion of a friend, who had paid for the copies supplied him; there being, however, no contract or implied contract with regard to the actual taking of the photograph, the general opinion of the Council was that the photographer could not sustain his right to the copyright.

A member remarked that the advertised price of hypo, although it had fallen, was still in excess of what the wholesale price justified.

The greater part of the evening was occupied in discussing certain propositions for the better carrying out of the objects of the association brought forward by Mr. Marcus Adams, and a committee was appointed to consider the same and report to the Council.

Commercial & Legal Intelligence.

NEW COMPANIES.

TEARNE AND SONS, LTD.—This private company was registered on December 20 with a capital of £5,000, in £1 shares. Objects: Transfer, colour and general printers, photographers, etc. The subscribers (each with one share) are: A. George, New Rose and Crown Inn, Robery, licensed victualler; F. E. Tearne, 22, All Saints Road, Birmingham, transfer manufacturer; A. J. L. Menzies, 22, All Saints Road, Birmingham, transfer manufacturer. First directors: A. George, F. E. Tearne, and A. J. L. Menzies. Registered office: 22, All Saints Road, Birmingham.

News and Notes.

BRITISH SCIENCE PRODUCTS AT MANCHESTER.—The exhibition now being held at the College of Technology shows the advances made in the application of science to British industry during the war. It is not confined to munitions entirely, but includes many branches which formerly were considered to be almost monopolies of Germany. Photographers will be interested principally in the lenses made for aeroplane work, which will prove useful in many other fields. Messrs. Aldis show two twenty-inch triplet lenses of very large aperture, one of which is pierced by shrapnel in action, but is still quite usable. Messrs. Taylor, Taylor, and Hobson, Ltd., show their "Aviar" lenses, and some very fine enlargements (24 x 18) from negatives made from the air with one of these lenses of 8½ in. focal length and aperture $f/4.5$. They claim that this lens is now considered superior to those made by Zeiss. Messrs. Dallmeyer also show their lenses for aerial photography and other work. Messrs. Adam Hilger show their light-filters in "flats," and both this firm and Messrs. Rheinberg show some wonderful "graticules," which are extremely fine scales produced on glass for measuring purposes in connection with microscopy and similar scientific work, as well as in artillery field-glasses. These are engraved on the surface of the glass by various photographic and semi-photographic processes. Messrs. Hilger exhibit the Abbé Refractometer and other instruments for the advanced research worker.

British Baryta-coated paper, produced by Messrs. Alex. Pirie and Sons, Ltd., of Bockburn, Aberdeenshire, is exhibited in the form of photographic prints of all sizes, mostly bromide and gaslight, of various well-known makers (Paget, Kosmos, Barnet), as well as some fine large prints by the ferro-prussiate and true-to-scale processes.

Chemicals for photographic use are shown by A. Boake, Roberts and Co., Ltd., Stratford, E. (sulphites), James Hurreough, Ltd., Lambeth, S.E.11 (Absolute alcohol, which was not made in this country previous to the war), Hopkin and Williams, Ltd., Hatton Garden (chemical reagents for research, replacing Kahlbaums), Johnson and Sons, Finsbury, E.C.2 (developers).

The United Alkali Co., Ltd., of Liverpool, show a varnish which they call "Duroprene." This should prove of great interest to photographers and apparatus makers on account of its extraordinary resistance to both acids and alkalis, as well as to atmospheric fumes of all kinds. It has been in use by the firm on metal, wood, and stone work exposed to the fumes of their own works, but has only just been placed on the market. This product is also being tentatively made in the form of translucent and tinted sheets. The resistant qualities of this varnish are shown by pieces of copper, etc., coated with it and immersed in various acids and alkalis (including ammonia) of 20 per cent. strength, as well as in petrol and alcohol. It is sold on the basis of 1lb. for one gallon.

In optical glass, the well-known firm of Chance, Bros., Smethwick, near Birmingham, show some large pieces, which compel expressions of admiration from the least technical-minded observer for their clearness and purity of substance. A disc for an astronomical telescope was shown, of the large diameter of 23 inches. The making of one like this usually takes over a year. Magnesium ribbon and aluminium powder are shown by several firms. Arc lamps are shown by the Westminster Engineering Co.

Correspondence.

- * * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- * * We do not undertake responsibility for the opinions expressed by our correspondents.

THE ASSISTANT QUESTION.

To the Editors.

Gentlemen, Judging by the correspondence in recent issues of the "B.J." there appears to be a growing interest in this very urgent and vital question.

Will every master and assistant who is in any way interested in the advancement of this matter of training of the assistant address to me a postcard to the Camera Club, 17, John Street, Adelphi, Strand, W.C.2? If sufficient evidence is forthcoming indicating that there is an earnest desire on the part of the persons concerned for this greater efficiency, it will spirit us with confidence further to develop the details of a scheme which has been under serious consideration for some time past. I would ask correspondents to express their ideas freely and frankly. The desire is to put into effect a scheme that will afford everyone an equal chance to gain by effort the skill needed by all assistants in the future.

This being so, opinions are required. So I hope your readers will not hesitate and think someone else will do all that's needed. It is their opportunity. Let them send a word, and thus help those who would help them. Awaiting their support, Yours sincerely,

MARCUS ADAMS.

THE PROBLEM OF HALATION.

To the Editors.

Gentlemen, Your "Ex Cathedra" remarks on halation are interesting and instructive, but we are still a long way from knowing all there is to know about halation and its prevention. The point that puzzles me, and possibly others is why some careful workers get halated negatives, while others do not, even when working on the same subject and under similar conditions. One must, I think, come to the conclusion that development is to a very, very large extent responsible for halated negatives.

An annual event at our local photographic society is a developing competition, and it has fallen to my lot each year to expose two or three dozen unbacked plates on the same subject, giving exactly the same exposure to each plate. A plate is given to each competitor to develop, he not knowing the subject, make of plate, or whether the plate was under, over, or accurately timed. The results obtained have been extraordinary in variety, particularly as regards halation—some showing it badly, others not at all.

For the last competition I selected a different subject, having the question of halation in mind. As two or three dozen plates have to be exposed under precisely the same conditions, landscapes or portraits are out of the question, and I always arrange a still life piece indoors and expose by meter. The subject in question consisted of two eggs in white egg-cups arranged against a clock in a dark oak case. The problem was, of course, to render the grain of the oak in the clock case without losing the delicate light and shade upon the eggs; and I also thought that the rapid appearance of the eggs on the negative would lead some competitors astray, especially if they watched the progress of development in a dish.

The results were most varied and interesting; the majority of the negatives showed the eggs very badly halated, while a few of the plates showed not the slightest trace of it. Why?

I asked the producer of the best negative how he developed, and his reply was: "I developed in the ordinary way; simply put it in a tank with some diluted developer, took the temperature, and timed it most carefully, and never saw the plate until it was ready for fixing." Older and more expert competitors made a terrible hash of their plates, though some of them worked with a tank and by time, as the winner did. I say this because enthusiastic tank users may be led to quote the instance given in order to support their views on tank development; but taken as a whole and putting

aside the best negative—dish-developed negatives were as good as those tanked

The facts given above, with others I have, lead me to believe that halation depends as much upon development as upon backing and make of plate, and I hope some enthusiastic and unbiassed worker will solve the problem.—Yours faithfully,
L. T. W.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed or reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

L. W.—Such materials were formerly obtainable from Mr. W. J. Barnes, Draper, 68, Upper Street, Islington, London, N., but we do not know whether, after four years of war time conditions, he has any to sell.

H. R.—The initials on your lens denote "Photographic Artists' Co-operative Supply Association." The True View lenses were rather indifferent rapid rectilinears with a full aperture of $f/8$. The 10 x 8 size was listed at £5 5s. in 1882.

J. C.—We are sorry we cannot give you any information from the data you supply. The numbers are only consecutive ones, and do not express a type. In any case, the lenses must be about sixty years old, and only worth a few shillings each.

W. M.—We think you will do well to retain the ground-glass, for, apart from equalising the light, the prints are usually of better quality. We think that if you place the arc further from the condenser you will get more even illumination. This adjustment should be made after focussing the image.

J. W.—The best suggestion we can make for caulking the joints of the box is marine glue, which you can obtain from a drysalter or, if not, from such a firm as Messrs. A. W. Penrose and Co., 109, Farringdon Road, E.C.1, but we think your best course would have been to have made the makers put the tank in proper condition.

T. E.—It would be very difficult to get a first-class man to give you the instruction you require, and in any case two weeks would be far too short a time, as you would require continuous instruction for that time. Your best plan would be to attend the Polytechnic day school at 309, Regent Street, London, W.1, where you can get expert teaching in the branches you mention.

W. G.—The cheapest method is to procure a changing-bag in which you can change your plates by touch; this is quite satisfactory if you are moderately careful. Do not trust to one that is fitted with eye-pieces or a slit to look through. The "Shepherd," sold by Houghtons at a pre-war price of 10s. 6d., is a very good one. It has eye-pieces, but they are easily blocked up. Practise a bit at home with old negatives. The Mackenzie-Wishart system is excellent. The slide costs 21s. in half-plate size and the envelopes 2s. each (pre-war prices). Messrs. Mackenzie and Co., 212, Old Dumbarton Road, Glasgow, will send full particulars on application.

A. C.—The lens is quite suitable, but must be stopped down to $f/11$ at the least to obtain sufficient depth of field; even then you will probably have to use the swing back to get the two rows into focus at once. With this aperture, using Johnson's flash powder, you will require about a small heaped-up teaspoonful as

a minimum, assuming that the walls of the room are fairly light, and that you use an Imperial flashlight plate, or one of similar speed; with dark walls and a slower plate, you may use up to double the quantity of powder. The powder should be spread out in a train on a flat piece of tin, which should be nailed on the top of a stick so that it can be held up to about 7 or 8 ft. high. This should be held about level with the camera, and about six feet to one side of it. You can use the touch paper supplied with the flash powder according to the directions given with it. As soon as the paper is lighted uncap the lens; it may take about 30 to 60 seconds before the flash goes off. Caution your sitters not to look up at the light, or they will have "blind eyes" in the picture. Use freshly mixed flash powder. It loses its actinic quality after a week or two. Remember that the powder is far more explosive than ordinary gunpowder, so do not leave the lid off the tin when the flash is to be fired.

STUDIO.—In my studio the light is on the north side, and is 7 ft. 10 in. square, beginning 3 ft. 5 ins. from the floor. I have done some very good things in it, but at the same time I want a little more light on the opposite side sometimes. Do you think that it would improve matters if I had a light put in the opposite side, which would be due south, and to control it with blinds? Or would it be better to put in a battery of half-watt lamps, not so much to take by night, but to assist the daylight when it is failing? In which case which system is best? To have the roof whitened and have 1,000-candle-power lamps with the light reflected up to the roof, and so get it soft, or to have the lamps put in in a half-circle and have them in a linen bob, each lamp being controlled by a separate switch?—J. B.

Either of the plans you suggest should answer very well. If you do not want to work at night, probably the south window would be cheaper and quite satisfactory. We do not much care for mixed day and artificial light if it can be avoided. If you have the half-watts, we should shut out the daylight altogether, and in that case we should arrange the lamps in a curve with linen or calico diffusers. You might have one reflected light from the roof, or you could have the lamps in open-top boxes so that you had both reflected and diffused light from the same lamp.

The British Journal of Photography.

IMPORTANT NOTICE.—Advertisers are requested to notice that the prices printed below represent an

Increased Scale of Charges,

which is now in operation in respect to all line announcements.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind this revised tariff. They will thus save themselves delay in the publication of their announcements.

Net Prepaid Line Advertisements.

Increased Tariff of Charges.

12 words or less	1/-
Extra words	1d. per word.

(No reduction for a series.)

Special Note. Adv'ts under a Box Number.

"Box No." and office address charged as 6 words.
For forwarding replies add 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.
Orders to repeat an adv't must be accompanied by the advertisement as previously printed.

Advertisements are not accepted over the telephone.

The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.

Displayed Adv'ts should reach the Publishers Monday morning.

The insertion of an Advertisement in any definite issue cannot be guaranteed.

The Summary of contents which usually occupies the lower half of this column will be found at the foot of the page overleaf and will continue to be placed there whilst its regular position is required for notices relating to the forthcoming "B.J. Almanac."

No More.

It must be announced that the whole edition of the British Journal Almanac for 1919 is now ordered, and no further copies can be supplied. The books of our publishers show that many dealers who have ordinarily supplied considerable numbers of the Almanac have this year so far not placed their orders. They, together with all the dealers throughout the country, have been simultaneously circularised by our publishers' sales department, and, therefore, the responsibility rests with them. Unfortunately, in the circumstances of restricted edition imposed by the scarcity of paper, the principle of "first come, first served" has necessarily had to be adopted.

Therefore, our advice to any reader of these lines who has not yet ordered a copy of the Almanac is that he should ascertain from his dealer whether a copy will be available; should the answer, in view of the fact stated in the previous paragraph, be in the negative, then the only remaining suggestion which it is possible for us to make is that the would-be purchaser should make application for a copy to some large dealer in London or the provinces who may perchance be able to supply him.

As regards the date of publication, we have endeavoured to arrange for the Almanac to be available to the trade throughout the United Kingdom at the end of January or during the first few days of February. It is just as well to say that we still hope to publish about this time, although the production of the printed sheets of the Almanac has been delayed a considerable number of days beyond the scheduled time. Therefore, it is possible that readers will require to wait for some days beyond the time already announced. Let us say that it is with a good deal of regret that we have had to submit to these variations, and uncertainties in the publication of the Almanac. In the years before the war its appearance to the day was a thing upon which our publishers prided themselves not a little. It may be hoped that with the 1920 edition they can resume their habit of punctuality.

EX CATHEDRA.

Enlargements for Finishing.

Labour is often wasted in working up enlargements because the enlarged print is too flat and soft to begin with; a print which might be a perfect reproduction of the tones of the original being often quite unsuitable for finishing, especially as it becomes difficult to preserve the likeness. If we start with a flat print we have to put in both light and shadow, and this not only calls for a much higher degree of skill but necessitates spending four or five times the amount of time which would be necessary with a more "contrasty" image. The following account of an experiment in this direction may be of some assistance to those who produce their own enlargements throughout. The original was a flat carbon bromide print of a three-quarter length figure from a negative about three inches by two and a 12 by 10 enlargement finished in black and white was required. A same-sized negative was made from this in the usual way using an ordinary plate, and as good an enlargement as was possible to obtain made from it. This proved to be full of detail, but was too even in tone all over to give an effective result. A second enlargement was made, giving a shorter exposure but this, while preserving what high lights were present in the original, was far too grey in the shadows. Another negative was made using a process plate which was developed as fully as possible, showing a decided improvement upon the ordinary plate. This was intensified with iodide of mercury, followed by amidol, and quite a brilliant image obtained. When enlarged the grain of the original was more evident than in the first result, but there was plenty of light and shade. Working up was done with black lead powder and pumice, the lights being taken out with a pointed rubber, and the final touches given with a black chalk pencil. The finished result was soft yet full of modelling, and such as might have been obtained from a good studio negative. Although in this case the work was done twice over, there was really no more trouble involved in making the successful enlargement than in the failure had the right plan been adopted at once. For the benefit of those who are not accustomed to using process plates it may be stated that these are quite suitable for ordinary copying, and that contrast is much more readily obtained while they are much more amenable to intensification than are ordinary or extra rapid plates.

The Best from Under-Exposure.

We are inclined to think that many operators, when developing plates that are known to have been grossly under-exposed through circumstances over which the photographer has no control, give too little time to the operation. Of course, if the negatives are required for press work the method which we describe below is not practicable on account of the long time taken. But in other circum-

stances, when a few hours do not greatly matter, we can recommend a trial of it. We do not claim, of course, that the procedure is a new one; but as the result of our own experience it is of very considerable value, and either entirely unknown or overlooked by the majority of photographers. Recently we exposed two plates of the non-screen ortho variety upon the same subject at exactly the same time, giving both the same exposure, which by a meter was only about a fifth what it should have been to secure the minimum correct exposure. These two plates were developed side by side in the same dish, using the time method, and the ordinary pyro-soda formula. When development had apparently come to a standstill one plate was taken out and fixed, while the other was left in the solution after dilution with about six times its own bulk of water. The dish was covered with a sheet of card and put aside for about an hour and a-half. The negative was then placed in a dish of plain water covered as before, and left until the next morning, when it was fixed and washed. Those two negatives, when examined side by side, amply justified the procedure. The first plate was weak, lacking in both tonal quality and shadow detail; while the second, though slightly pyro-stained, was of quite good printing quality, nor was there any tendency towards "grain," which would certainly have been the case if development had been unduly forced.

* * *

Sketch Portraits.

One of the things that the sketch photographer needs to be careful about is the manner in which the sitter is placed on the plate. Recently we saw an instance of this in the head and shoulders portrait of an army officer. The camera was evidently much too high, and the resulting picture gave the impression that one was looking down upon the sitter's head, while at the same time, due to an uncomfortable pose, the sitter was falling forward, as it were, into the picture. Whether that particular picture satisfied the sitter we do not know, but it should not have satisfied the photographer. Many photographers, when posing their sitters for a sketch portrait, pay little or no attention to the general attitude of the body. Yet if this is neglected it is next to impossible to obtain a satisfactory pose of the head. The arms frequently cause trouble in this way, and if care is not taken give a humpy or round-shouldered appearance to the sitter. The showcases of many photographers furnish abundant evidence of the fact that the trunk of the sitter's body was not posed in a comfortable position or even a natural one; though only a head and

shoulders portrait is to be taken, it is impossible to obtain the best results if attention to these minor details is not given.

* * *

Strip Tests in Carbon Printing.

One of the greatest difficulties encountered by the beginner in carbon printing is the correct estimation of exposure. The experienced printer can tell at a glance how many "tints" a certain negative will require, but a novice is quite at sea and spoils much tissue in arriving at even a passable result. To such we recommend the adoption of the strip-testing system as practised in bromide printing, and, as it is not practicable to hold the shading card while the actinometer is working, a little mechanical device becomes necessary. This is made by cutting three pieces of opaque card the width of the inside of the opening of the printing-frame, one piece being a quarter the length of the plate, one half the length, and the third three-quarters of the length. For example, if the front of the frame has a clear opening of six inches by four we shall require one piece four by one and a half, one four by three, and one four by four and a half. If we take a fairly strong negative we may give the whole of it one tint, then drop on the narrow strip and give another tint, then the half-way strip and the three-quarter strip, giving a tint after adding each. We shall then get a print one end of which has had one tint while the other has had four tints, two and three intervening. Developing should be done in rather cool water, not over 80 degrees, and we shall then see which exposure is most suitable for the negative. If this test be applied to half a dozen negatives differing as widely as possible we shall get a set of typical densities with their correct exposures. Of course, many negatives will print with less than one tint, and in this case it would be perhaps better to adopt one of the "step" actinometers. In any case, all that is necessary is to establish a definite relation between the actinometer tint and the density of the negative. This does not make any allowance for the varying rapidity of the tissue, but it is assumed that the printer will not overlook this point.

BUYING EQUIPMENT.

STARTING a photographic business resembles in many respects setting up housekeeping; that is to say, there is a natural tendency to spend an undue proportion of the sum allotted for the purpose on certain big items and to stint on less showy but more essential details—in other

SUMMARY.

The second annual report of the Society of Chemical Industry, dealing with progress in photographic manufacture during 1917, forms an excellent guide to the subject. (P. 13.)

Errors which are likely to be committed when purchasing the appliances and fittings for a new photographic business are dealt with in an article on page 10.

At the Royal Photographic Society, on Tuesday evening last, a demonstration was given of a new photographic material, Kerotype paper, providing very wide facilities for the making of prints on any description of paper, and on other materials, such as wood, metal, silk or satin. The paper is developed in the first instance exactly like a bromide or a gaslight paper. (P. 16.)

The camera and lens, with critical remarks upon the various fittings and suggestions for securing the most practical outfits, form the matter of an article by "Practicus" on page 11.

Some practical hints on "strip printing," including the securing of uniform exposures and conveniences in developing, are given on page 15.

A letter from an assistant on the education question, and others on aero-photography and town planning, the all-round man, and

the substitution of soda salts for those of potash find a place under "Correspondence." (P. 18.)

An account of yet another exhibition of war photographs, which was opened at the Grafton Galleries on Tuesday last, is given on page 16.

The usefulness of carrying a small repair outfit, on that of the cyclists' model, when engaged in outdoor work, is demonstrated on page 15.

A note on a new booklet on the use of Wratten M-filters will be found on page 18.

The quality of an enlargement greatly influences the amount of work necessary to produce a well finished effect. A note on this point, with practical suggestions, will be found on page 9.

How to obtain the best result from a plate which has received insufficient exposure is the subject of a note on page 9.

The applicability of the "strip test" system, to enable beginners in carbon printing to obtain correct exposure, is pointed out on page 10.

Mending vulcanite articles, waterproof linings for sinks and dishes, developing materials, and the extra-sensitising of plates are among the subjects dealt with in "Answers to Correspondents." (P. 17.)

words, to purchase suites and decorations for the reception and perhaps the bedrooms, and to neglect the kitchen and scullery. In the photographer's case this has its equivalent in buying a large and elaborate camera outfit, a quantity of furniture and backgrounds, and making shift with inferior appliances in the dark and printing-rooms.

An experienced chemist once said that when equipping a laboratory it could be assumed that after finding the cost of the principal pieces of apparatus, which the inexperienced imagined represented the bulk of the outlay, an equal amount should be allowed for sundries, which need not be purchased all at once but as required. We recently found confirmation of this judgment in the remark which a beginner in portraiture made in reply to a question as to how the business was progressing. It was to the effect that the takings were quite satisfactory, but that he had not received much benefit, as there was always something else to buy.

If a little more judgment had been exercised in the first outlay there would have been a surplus available, and the profits of the first few months would not have been swallowed up as quickly as they were made. In our friend's case success came quickly, and he could live and still get what was needed; but very often it takes some months before running expenses are covered and anything that can be called a profit made.

There is always a temptation to go in for a big studio camera. A twelve by ten with lenses to suit is usually the minimum, but the old hand knows that this size is now rarely required for direct portrait work in most studios. We can, therefore, economise by getting a good whole-plate outfit and keep something in hand for the outdoor apparatus, which should be of the larger size. Any panel portraits or studio groups can be quite well taken with a good field camera and lens, and in other cases large prints can easily be made by enlarging. We are apt to forget that developing papers are now almost exclusively used, and that if only a moderate size is required there is no need to mention the fact that the prints are not made by contact. This brings us to the question of enlarging apparatus. Wherever it is possible this should be installed from the first, as it will soon save its cost, and it is preferable to select the lantern form instead of a daylight apparatus—however, the latter is better than nothing, and even a fixed focus box giving an enlargement of two diameters will be found of great value, as it enables a cabinet negative to be enlarged to twelve by ten almost as easily as the making of a contact print. As an example of the value and practicability of enlarging we may mention an order for a number of full-sized reproductions of pen-and-ink designs. These were photographed upon half-plates, and enlarged to fifteen by twelve. The difference in the price of the small and large plates made a very

substantial increase in the profit on the job, and the customer was not a penny the worse.

Great economy can be effected by properly equipping the dark-room, especially now that so much bromide work is done. Plenty of sink accommodation should be provided, and if lead be found too costly asphalt sheeting can be used as lining. It should be remembered that bench room can always be obtained by covering a sink with boards, but it is impossible to reverse the process. An efficient lamp with red and yellow filters is needed, and it is a good plan to provide a second one for the general illumination of the room; this will prevent many break-ages. A good printing box taking negatives up to whole-plate is almost a necessity nowadays even in the smallest business, for the little man who has to do every stroke himself must not have to waste time with printing frames. An ample number of dishes for developing, fixing, and washing should be provided, the larger ones being of wood lined with some waterproof material, and the smaller ones of porcelain. Vulcanite and celluloid are best avoided for professional work.

We may now return to the studio, and consider the question of backgrounds. Where it is possible one end wall should be finished so as to serve as an interior; in addition, we require a very dark and a white ground with continuous floorcloth. When funds permit a piece of bold-patterned tapestry may be added, but scenic backgrounds are not needed except for the cheapest class of work. Chairs and tables should be, as a rule, light and dainty, such as people use every day, and not specially designed for photographic use. A heavy oak chair is a useful accessory when it is necessary to take the mayor or other celebrity.

In the work-room especial care should be taken to facilitate output. It never should be necessary to clear the apparatus necessary for one operation before another can be started. There should be places for attaching tissue, trimming, and mounting, and these spaces should never be encroached upon.

Retouching desks should be ample in size and firmly made. Anyone with the least mechanical ability can make a good desk in an hour or two, always bearing in mind that the desk is made for the use of a human being and not for a negative. It is absurd to talk about quarter-plate and half-plate desks when they are supposed to accommodate a well-grown man or woman.

It is necessary to decide what to buy before entering the dealer's portals, or it is likely that a lot of unnecessary stuff will be obtained. The purchaser should know better than the salesman what he requires, and it is only natural for the latter to try and shift such goods as are rather slow in selling. We shall not harm the dealer by this advice, his bill will come to the same, but if the tyro makes his own choice he should get what he really needs.

PRACTICUS IN THE STUDIO.

THE CAMERA AND LENS.

THE selection of the studio camera and lens, or rather lenses, for it is a serious handicap to have to work with one only, deserves the most careful consideration, and in comparison with other items a liberal allotment should be made when planning your outlay. A badly made camera or an inferior lens will soon cause the loss of more money than is saved on their cost, and will do much to brand the work turned out as second class or worse. The operator should never work with the feeling that he could do better if he had better apparatus. Now I do not want to convey the idea that such apparatus

should necessarily be costly, and as an instance of this I may say that I recently selected for a young friend a 12 x 10 outfit, comprising camera, studio stand, a 12 in. $f/4$ portrait lens, and a 5 D. Dallmeyer $f/6$, at a total cost of less than £25, all being purchased from well-known London dealers.

Broadly speaking, there are two models of studio camera: the British pattern, as made by Hare, Watson, and several other makers, and the German model, which has been extensively copied by English makers. For practical purposes there is little to choose between them. When choosing a camera

it is desirable to have one which is not permanently built into its stand, as in the case of any accident to the latter the whole outfit is rendered useless; besides this, it is impossible to get the camera near the floor, which is often necessary when taking children's portraits.

Movements essential to the studio camera are rack and pinion or screw focussing. Personally I prefer the latter, although it is considered rather out of date now, as it never gives trouble by becoming loose and allowing the back to move, besides being conveniently placed in a fixed position. There should be vertical and side wings to the back and a rising front; the bellows should be of ample length, bearing in mind that lenses of much greater focal length are now used than was formerly the case. Twenty-four inches is not an uncommon length, so that for a 4½-in. head on a 12 x 10 plate we require an extension of 36 ins. This should not be lost sight of, if one is offered an otherwise suitable camera of old pattern, although the defect may be remedied by fitting a cone extension or "box front." Whatever camera is selected it should be well cared for and not allowed to become covered with the black greasy patches one too often sees. In passing I may remark that ordinary spirits of turpentine is an excellent medium for cleaning dirty woodwork, and an hour's work with it, followed by some good furniture cream, will often make a camera and stand look worth 50 per cent. more than when you started.

It is very usual to fix repeating backs so that two half- or quarter-plates can be used side by side. This is a survival of wet plate days, when it was no more trouble to coat and sensitise a whole-plate than one-half or quarter the size. I think that the American plan of "one slide, one exposure" much more handy and safe. Many of the American studio stands have racks on either side, one for unexposed and the other for exposed, a dozen or more cheap single slides each for a 7 x 5 (American half-plate) being supplied with the camera. Double exposures can then only be made by the grossest carelessness. Another "Yankee notion" which is a good one is to make the pushing of the slide into the exposing position open the shutter. This has been improved upon by Messrs. Dallmeyer, who introduced a back in which double flap exposing shutter slipped along with the slide, so that the lens did not require covering before the slide was opened; this saves much time. In my opinion, any camera-maker who would supply such a device fitted with a number of *cheap* slides would find his reward. Think of the convenience of being able to make a couple of dozen exposures without having to refill.

If the ordinary stands do not seem satisfactory to you, the platform style, of which the Hana and the Semi-Centennial are the best known examples, will probably meet all requirements. In these a platform carrying the camera travels between two uprights, and the camera may be placed as high as an ordinary person can see to focus at or lowered to a few inches from the floor, the castors should be rubber-shod, and, if possible, a brake fitted, so that there is no risk of moving the camera when inserting the slide. The lens shutter is an important feature in studio apparatus, and the rubber fittings thereof have probably conducted to more profanity than all the rest of the outfit. I like the feel of a ball and tube while it is in good condition, but that is usually only for a brief period, before it begins playing tricks before an important sitter. The Bowden wire cable or "Antinous" release is much more reliable, and would be better if the bicycle cable were used instead of the weaker form usually fitted. The pressure button, too, is particularly annoying, as one cannot grab it anyhow as one can the rubber bulb, but must get hold of it just right between the fingers. It would be quite easy to make a pear-shaped handle to work like the rubber one, and if the makers want a sketch for it I will send them one, but that will probably not be till the patent has expired.

Now for the shutter itself, after having relieved my feelings about releases. The best shutter I have ever used, and I think I have worked with nearly every pattern, is an American one, the Packard Ideal. There are several shutters, none British, of this pattern, which are probably nearly if not quite as good. It is made on the sector principle, with vulcanite leaves, and the working parts are balanced, so that very little pressure is required to actuate it. Let me confess it works best with a rubber ball and tube, the only disadvantage of which is that the rubber is too hard and the ball splits; still, if you substitute a good English bulb this trouble vanishes. The next best shutter is the velvet flap, originally introduced by Mr. James Cadett, and still in use in the majority of studios under the name of the Guerry shutter. Why an English shutter had to be made in France and sold under a French name I cannot say, but so it is. The hemispherical bellows, or Gröndner's shutter, is fairly satisfactory, but the interior bellows is troublesome. With the Antinous release it is much better, although the leather bellows which forms the shutter is easily injured by a careless operator; still, on the whole, it is a good shutter.

No less important than the camera is the lens; in fact, although with a faulty camera and a good lens we may produce excellent results, it is impossible to reverse the conditions and do so with a faulty lens upon the finest camera. The requirements of different studios vary so greatly that it is difficult to suggest the most suitable all-round selection. The length of the studio is an important factor, and I feel that I cannot do better than to refer the reader to the table dealing with the subject in the B.J. Almanac. Next in importance is the type of lens. Of late years there has been a growing tendency to oust the time-honoured Petzval or Dallmeyer types in favour of the rapid anastigmats. There are two sides to the question, and these have been little discussed. The anastigmat is unquestionably far superior to the portrait lens, when tried to its fullest extent, but it loses this position when only a small portion of its field is being utilised, as its cost is much greater and its qualities are wasted. If I were selecting lenses for a short studio, say, an eight-inch for cabinets and a twelve-inch for whole-plate standing figures, my choice would be an *f*/4.5 anastigmat of the desired focus, but if I could use a fourteen or sixteen-inch lens for cabinets I think that I should go for a portrait lens, which I could get at much less cost and which would possibly be fitted with a "diffusion of focus" adjustment. One point which I would specially impress upon the purchaser is to choose as long focus a lens as his studio will accommodate for the greater part of the work to be done. If the studio be very short, so that a 6½ or 7-inch lens has to be used for full-length cabinets, it is better to obtain at least a ten-inch lens for heads and half-lengths and to get a smaller lens for the full lengths. There are now some very cheap anastigmats which work well, with apertures of *f*/6 to *f*/7.7, to be purchased at prices which were formerly charged for common foreign rectilinears, and these will answer for short-focus portrait work.

There is a growing demand for soft definition in portraiture. By this I do not mean absolute fuzziness such as some selecting committees used to revel in, but a general softening of outline and suppression of small detail without loss of texture. To secure this many lenses have been introduced, and I have made negatives with most of them. The majority give too great an amount of diffusion at full aperture, and when stopped down to reduce this the exposures are unduly prolonged. For the everyday professional who wishes to make an essay in this direction I would suggest the use of the "patent" portrait lens of Dallmeyer, the recent portrait lenses of Ross, and the Cooke portrait lens. All these have adjustments which allow of any degree of diffusion up to a certain point being introduced at will, while in the case of the Ross and Dallmeyer lens a

further stage may be attained by removing the back combination and using the front lens *per se* and *in situ*. There are many nameless portrait lenses, very bad as a whole, which would make excellent soft focus lenses if the back combination were taken out and lost. It should be remembered that the front lens of a portrait lens usually requires only slightly more than double the exposure of the complete lens, and not four times, as is the case with a rectilinear. The focussing eye-piece or

magnifier is a very useful little adjunct to the camera outfit, as it saves eye strain and makes for certainty in focussing, especially in copying. One of fairly good quality of the Ramsden pattern will be found most satisfactory, as the field is flat and the definition good. The cheap forms with single lenses have too much spherical and chromatic aberration to be used by anyone not skilled in optical observation, and those who are would not give them house room. PRACTICUS.

PHOTOGRAPHIC MATERIALS AND PROCESSES.

[We are glad of the opportunity of publishing the second of the annual reports on progress in photographic manufacture which has been issued by the Society of Chemical Industry. The author is again Mr. B. V. Storr, M.Sc., of the Ilford Company, to whom students of the technical and scientific side of photography will feel indebted for his analysis of what has been published and accomplished during the period under review, that is to say, the year 1917. We should point out that the reference "J" which figures frequently in the footnotes is to the "Journal of the Society of Chemical Industry." It will, of course, be noted that the report is one which had been completed some considerable time ago. Apparently it is not possible for the Society to bring these reviews out closer to date, although we should have thought that less than a year might be allowed to elapse before the completion of the reviewed period and the publication of the report.—EDS. "H. J."]

APART from work on the production and perfecting of a satisfactory colour cinematograph process, it is probable that the chief photographic effort in the past eighteen months has been towards the improvement of methods particularly adapted to problems of the war. Exactly what has been accomplished in this direction is not yet disclosed to the general public, although some indications have been given in the form of special photographs such as those shown at the last exhibition of the Royal Photographic Society.

On the whole the general manufacturing conditions have been getting gradually more and more difficult, although in some directions there has been an easement. Bromides, which reached a maximum price of about 25s. per lb. in 1916, have settled down again to about 5s. per lb., while silver, which reached a record price of just over 4s. 6d. per oz. troy, has dropped again to somewhat nearer its normal price. Gold chloride, on the other hand, has increased in price by about 25 per cent. Gelatine and all kinds of paper have been getting steadily scarcer and dearer, and owing to their own particular circumstances the manufacturers have found difficulty in maintaining their former standard. The condition of the glass market has compelled manufacturers to make use of renovated negative glass. The general effect of the entry of the United States into the war is not yet fully evident, but it appears highly probable that supplies of some of the raw materials will be still more restricted.

The general position on some smaller though essential points has improved greatly. In addition to metal substitutes, metal itself is now being produced in this country as well as *p*-aminophenol, which latter is also being made in Canada; in Australia the manufacture of pyrogallol acid and amidol has been undertaken by a department of the government. The position in enemy countries is not known with certainty, but the patented process of Pape' to resuscitate old developers by the addition of alkali is suggestive. Schering' improves baryta-coated papers by a further coating of albumen, and Lüpke-Cramer' makes the suggestion to improve packing papers by impregnation with manganese dioxide.

The production of sensitising dyes to replace those in general use before the war has been successfully accomplished by W. J. Pöpe,' under whose direction are now being made, for Ilford, limited, semitol red and green (German pinacyanol and pinaverdöl) and a new sensitiser, sensitol violet, in addition to erythrosin and a number of dyes used for making photographic light-filters. These are being used both in this country and in the United States.

Negative Processes.

There is little of actual progress to record in negative processes. The attempt to increase the effective speed of X-ray plates is being

made in several directions, but no serious advance can as yet be reported. Baker' increases X-ray speed by the use of two intensifying screens, one in front of the film, very transparent to X-rays, and one behind the film less transparent; Edwards' for the same purpose proposes to coat celluloid film on both sides with emulsion. Paria and Picard' have extended their patent with respect to phosphorescent substances to include the use of phosphorescent zinc sulphide as a substratum screen, a film of gelatinous alumina being precipitated on the sulphide to prevent contact with the sensitive coating.

La Rougery' has patented the production of a special negative paper by high-temperature calendering and pressure and Hudson' the process of using an ordinary white paper or card for negative purposes, prints being obtained by reflected light. Sosna and Ruedebach' have extended their list of dyes used to prevent dark-room fog, etc., to include phenolphthalein, which turns red in alkaline developers—a process very similar in principle to the old method of using a dye in the developer.

Several of the processes of manipulation have received considerable attention. Crabtree,' of the Kodak Research Laboratory, has a paper on development at high temperatures such as are frequent in tropical countries. The chief hardening agents are formalin, alum, and chrome alum, which may be employed before, during, or after development; the method recommended is to use a *p*-aminophenol developer, which causes very little swelling of the gelatine, followed by a plain fixing bath, a chrome-alum fixing bath, or a formalin fixing bath according to the temperature. In the experiments 95°F. (35°C.) was taken as the maximum which need be considered. An interesting method of using a two-solution developer is given by North,' who treats the plate first with the solution of reducer and then with the alkali, a method which has the effect under suitable conditions of restraining the denser parts of the image and allowing full development of the light tones. *p*-Phenylenediamine or quinol with ammonium chloride' is recommended as developer when fineness of grain is desired, the slight solvent action of these substances on the silver salt assisting in this direction; Koch and du Prél,' however, attribute the effect to a development of part only of the silver bromide granule. Brewster' patents the use of the same developer, combined with nitrate, for development of a wide range of exposures; both substances were, of course, known already as preventives of reversal when present in the film during exposure.

Ross,¹⁸ for the production of stellar images, recommends the use of a quinol and alkali hydroxide developer as giving clean-cut images, a practice in agreement with that of process workers. In this connection some experiments of Campbell¹⁹ and Turner²⁰ are interesting. The former, by measurements of spectrograms, obtained smaller readings for the separation of pairs of lines than were given by Rowland's tables. The latter got a similar effect in crossed images of a rescan when the lines approached within a certain limiting distance and suggests some mutual effect between the images: it would be interesting to know to what extent this effect could be explained by a disturbance of the mass centres of slightly separated images by reason of the overlapping of the fringes between them, and also whether an actual slight displacement of the lines towards one another is produced in the drying of the plates by reason of the hardening of the film between the lines as compared with that on either side.

Hochstetter²¹ has patented a combined developing and fixing bath which contains thiosulphate and glycerine, with citrate apparently as restrainer.

The general question of fixing and washing has been examined by Elsdon²² and Warwick.²³ The former determined the rate of removal of thiosulphate from a gelatine film by successive washings and found no evidence of adsorption. The actual time necessary for complete removal will of course depend upon the amount of thiosulphate present, but chiefly upon the rate at which equilibrium is attained between the film and the washing water, this being a function of the nature of the gelatine film and temperature. Warwick found the same general rule to apply and examined also the behaviour of papers, where the absorbent base complicates the problem, and the method of washing in running water. In a further paper Warwick²⁴ considers the rate of removal of the silver salt by thiosulphate, the normal law being again followed. The rate is dependent on the strength of the hypo solution, a maximum being reached at about 40 per cent. and a zero rate at saturation point. He used a silver sulphide tint method for estimating the quantity of silver. His general conclusion as to the correctness of the advice usually given to fix for twice as long as is required to "clear" the film is combated by the Editor of the "Photographic Journal of America,"²⁵ who found that thorough washing completely removed all the silver from plates taken from the fixing bath immediately all turbidity had disappeared.

Weinhandler and Simpson²⁶ patent a method of destroying thiosulphate and salts of weak sulphur acids by means of hypochlorite produced by the electrolysis of sodium chloride solution containing products or negatives.

Bainbridge²⁷ recommends the permanganate test as the most delicate for thiosulphate, an indication being given by degradation of tint even at a dilution of 1 in 15,000,000; the mercurous nitrate test is more affected by common impurities and indicates only up to 1 in 2,000,000.

A considerable amount of discussion has centred round the properties of various reducing solutions, a desideratum being a reducer having an effect proportional to the depth of image. Huse and Nietz,²⁸ following up a suggestion of Deck,²⁹ examined the effect of combined permanganate and persulphate, and also that of hypochlorite,³⁰ both reducers being nearly proportional. Becher and Winterstein³¹ have examined the action of iodine both alone and combined with thiourea and with cyanide; they give also a general classification of the best known reducers. Greena³² examined mixtures of thiosulphate and persulphate, which are much steadier in action than persulphate alone. Gear³³ calls attention to the

preserving action of potassium bromide, manna, and glucose on ferricyanide solutions. Smith³⁴ recommends ammonio-copper sulphate in place of ferricyanide now that the latter is so expensive.

A paper by Crabtree³⁵ describes the variation of flash powders with their composition, both as to the metal and the oxidiser used, with the fineness of division of the metal and with the arrangement when fired. A mixture containing sodium oxalate, red phosphorus, a metallic powder such as magnesium or a mixture of magnesium and aluminium, and a substance such as strontium nitrate, is patented³⁶ by him for the Eastman Kodak Co.

Wedekind³⁷ has patented the use of metals such as zirconium, thorium, and titanium, mixed with their nitrates or chlorates for the production of smokeless and odourless flash-powders.

Crowther³⁸ has examined the chemical reactions involved in the chromium intensification process first suggested by Eder and afterwards modified and expanded by Piper and Carnegie in 1905. With Eder's original formula in which a higher proportion of acid is used than in any of the modifications suggested and which leads to only slight intensification, there does not appear to be any chromium compound attached to the bleached image. In the case of the other three formulæ given by Piper and Carnegie, where the intensification obtained increases as the proportion of acid is reduced, the amount of attached chromium also increases; in the extreme case this appears to be partly chromium hydroxide and partly chromium trioxide, the latter imparting a brown colour, and in the other cases only the hydroxide.

Positive Processes.

The supply of platinum is still too limited for it to be available for photographic purposes. General Thayer³⁹ is said to have discovered a considerable source of it in the Adirondacks, but that has not yet materialised. The Platinotype Company have introduced "Palladiotype" in which palladium is used to give effects very similar to those of platinum, and the use of palladium as a toning agent for collodion paper facilitated by a bath which contains ammonium chloride, sodium glycolate, and succinic acid and does not require a special fixing bath, has been recommended by Valenta.⁴⁰ The latter has also investigated the properties of salts of diglycolatoferrie acid⁴¹ from which an excellent blue printing paper can be obtained, but of poor keeping qualities. Valenta⁴² also draws attention to the fact that Sulzberger's patent on the use of ferrocyanide (mentioned in the last report) was forestalled by Fox Talbot in 1839 and that the process was mentioned in Eder's *Handbuch*.

Strasser⁴³ has worked out a toning method with the use of Schlippe's salt; Sehering⁴⁴ has improved his original selenium toning bath. Nietz and Huse⁴⁵ have worked out in some detail the possibilities of obtaining sepia tones by the use of strongly restrained developers. Very few papers give good tones by this process; the best results are obtained by a chloro-quinol developer containing bromide and metabisulphite and necessitating an increase of exposure of from 75 to 100 times that required by normal developers.

Spitzer and Wilhelm⁴⁶ have patented a combined toning and fixing bath containing tellurous or telluric acid or their salts along with thiosulphate.

Two patents for transfer processes have been brought out, one by Pin⁴⁷ for film in which coconut oil soap is the chief stripping agent, and one by Kent and Middleton⁴⁸ for paper, using paraffin wax. A transferotype bromide paper on similar lines has been introduced by the Kodak Co.

In process and allied work, Bull, Smith, and Turner⁴⁹ have a paper on some of the intricacies of the half-tone process, Fishenden⁵⁰

on the photographic engraving of rollers for intaglio printing, and Crabtree²¹ on the advantage of using citric and oxalic acids respectively in the preparation of zinc and aluminium plates for lithographs. Dorian²² has patented the use of a half-tone screen composed of small lenticular grains, preferably coloured (see also Knudson; Ann. Rep. 1, 303). Rieder²³ obtains an intaglio printing surface by forming a screen surface in bichromated fish glue and getting a positive over that in caoutchouc and asphalt; Orans,²⁴ for ease of correction, prints on emulsion coated on a serrated surface of the type of a Levy screen on celluloid or celluloid on glass.

Meadway²⁵ uses a mixture of naphthalene and a white metal, with rubber as adhesive, as coating for a projection screen, while Bebbington²⁶ coats a support such as glass, gelatine, or waxed paper with a dull blue-coloured solution and projects on to that side, the audience facing the other side.

An interesting account is given by Warburg²⁷ of the work of Meissling on the use of dyes such as erythrosine and auramine as hardening agents in the carbon and gum processes, an effect which is attributed to the formation of formalin. The erythrosin preparations are said to be quite equal to those containing bichromate and to have better keeping qualities. B. V. STORR, M.Sc.

(To be continued.)

STRIP PRINTING.

(From Rajar "Trade Notes.")

THE method of printing bromides in strips either "three on" or "six on" is, to judge by our ever increasing sales, becoming more popular than ever both for postcards and larger work. This month we propose to offer a friendly criticism of some of the methods of working that have come under our observation.

The chief trouble seems to be in getting all the images the same depth, and we think that in most cases it is not the assistant who is to blame, but the method. The exposing light may be so powerful that the exposure necessary is only a fraction of a second, and it becomes an easy matter to make a 50 per cent. or even a 100 per cent. error. The light should be screened down or a lower candle-power light used, so that at least two or three seconds exposure is required; the extra time so occupied would be saved by the absence of "repeats," and better all-round work would result. In counting seconds it is better to count quickly—one-two-three-four, one; one-two-three-four, two; and so on. A loud-ticking clock will serve as an accurate guide.

Another defect often met with is the incorrect placing of a vignettted head on postcard strips, with the result that upon trimming the head is on one side of the card. To prevent this, it is a good plan to get a waste postcard, exactly 5½ by 3½, and cut out an oval opening about 3½ by 2½ in the centre, or a little higher. When adjusting the negative in the carrier the cut-out postcard is placed on it, taking care to see that the card is in the correct first "feed" mark.

Another trouble is "air-bells" in development or fixing. The chances of getting these in development can be reduced to a minimum by placing the strips in the developer in pairs, back to back. We have seen many skillful assistants work this way, using the right hand to pair them and the left hand to place them in the developer and turn them over. Up to a dozen pairs can be handled in this way, taking care to keep them in the order in which they go into the developer, and to use plenty of solution. With the finger and thumb it is an easy matter to pick out the bottom pair, place it at the top, and so on, removing the pairs one by one as they become fully developed. When thrown in the fixing bath an assistant should at once part the pairs and fully immerse them, afterwards keeping them on the move. It is true that perfect fixation is more important than thorough washing, and it is equally true that the first minute of a print's immersion in the fixing bath is the most important, and the fixing solution should have free access to both back and front of the print.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

A Camera Repair-Outfit.

ONLY one photographer have I ever met who habitually carried a repair-outfit when going on outdoor jobs, and his practice consisted principally in twelve-by-ten and whole-plate work at a distance from his headquarters. It is an idea that is well worth following, because, although the occasion for its use may never arise at all when out on a job, there is always the possibility of an accident when the means of a make-shift repair may save the job. In addition to this, there are cases when the movements of the camera are strained to their limits to include an extremely high building, or for other reasons that will occur to all outdoor operators. On such occasions as these a little slackening or even temporary removal of a few screws will prevent that strain and permit of a little extra extension of the movement.

There is no reason why the repair outfit should be larger than those supplied for cycles. A small screwdriver, as sold for watch-makers, sewing machines, or fretwork will be the largest item, then a small drill bit or bradawl fixed in a handle, obtainable at any fretwork shop, and a tiny half-round file will complete the list of tools. A small screw eye or two are often handy in several ways and take the place of a gimlet. A small assortment of screws, steel pins or needles, a small tube of fish-glue, and a bit of strong thread or "flex," can all be packed in a little tin, and will cope with almost any emergency.—CHARLES.

The Tyro's First Camera.

IT is a curious fact that most people who obtain a camera (either by purchase or as a gift) soon begin to wish for some other kind. Now, every girl or boy who takes up photography as a living ought to have a camera. No one gets the real enthusiasm for the work that will get him on if he is satisfied with printing from other folks' negatives.

The best all round camera to start with for pretty well every possible reason is a quarter plate stand camera with a double extension, an ordinary R.R. lens, and a simple shutter, preferably a roller-blind. In addition to being the right sort of camera to learn most things from in a practical way it has several other strong advantages. One is that the necessary focussing and other operations preliminary to exposing the plate foster a care for ensuring that all this trouble will not be wasted by wrong exposure and careless afterwork. A magazine camera has exactly the opposite effect. Thus, from the very start with the stand camera one gets a bigger and far more encouraging proportion of successes.

Next, the tyro is sure, contrary to the oft repeated text-book advice, to try his hand at portraiture, and the ability to focus properly is essential for this work. One more reason for the choice recommended, and a very strong one indeed, is that at the second-hand dealers' this particular type of camera is least in demand, and a bargain can often be secured, so that the initial outlay need not be great. The buying of the second camera, when the beginner's inclinations begin to indicate the most suitable type of instrument, will therefore be not such a costly matter, and the original quarter-plate camera will be found useful for many years afterwards, for lantern-slide making, or to form part of a copying or enlarging installation. KINGSTON.

FORTHCOMING EXHIBITIONS.

February 20 to 22.—Leicester and Leicestershire Photographic Society. Secretary, H. C. Cross, 80, Harrow Road, Leicester.

February 22 to March 8.—Edinburgh Photographic Society. Entries close February 13. Secretary, George Masie, 10, Hart Street, Edinburgh.

BARNET PLATES AND PAPERS. Messrs. Elliott and Sons, Barnet, Herts, send us a most artistic showcard, small in size but choice in character, calling attention to their plates and papers. The card is also a calendar for the present year, and we have no doubt that any dealer who has not received one will be glad to have a copy as a decorative item in his establishment.

Exhibitions.

CANADIAN OFFICIAL WAR PHOTOGRAPHS.

An exhibition—it may be supposed the last—of war photographs was opened on Tuesday last at the Grafton Galleries, Old Bond Street, London, W., by Sir Edward Kemp, the Canadian Overseas Minister. It comprises, within about 130 photographic enlargements, scenes and incidents of the several months of strenuous fighting prior to the signing of the armistice. The photographs present a tragic picture of the ruin which marked the territory within which the Canadians fought in their last advance from Amiens to Cambrai, from thence to Mons. Cambrai itself, as shown by the photograph, is a scene of awful desolation, the culmination of the ruin with which the Germans compassed it by fire before the Canadians entered it. A similar photograph shows the same fate of the old town of Valenciennes, the photographer having succeeded in photographing the conflagration itself. Other photographs depict the lighter side of warfare. What is described as "the largest photograph in the world" is a band of picture measuring, we are told, 200 ft. long and about 1 yard in width. It runs as a frieze round the whole of the gallery, and represents guns captured from the enemy. A word remains to be said for the excellent photographic quality and colouring of the enlargements, which, so we learn from the catalogue, are the work of Messrs. Raines, of Ealing. The exhibition is open to the public on weekdays from 10 a.m. to 6 p.m., and on Sundays from 3 p.m. to 6 p.m.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, December 9-21.

SHUTTERS.—No. 20,900. Photographic Shutters. S. G. and W. H. Arkell.

PLATES.—No. 20,580. Photographic Plates and Negatives. G. E. H. Rawlins.

FILM.—No. 20,951. Roll Photographic Film. W. G. Fisk.

CINEMATOGRAPHY.—No. 21,296. Cinematograph Apparatus. A. Garbarini, G. Gautier, and L. Mancaire.

LENSES.—No. 21,200. Means for Adjusting and Indicating Focus of Camera Lenses. J. F. Mongiardino.

DARK-ROOM LAMPS.—No. 21,234. Dark-room Lamps. B. L. Oldfield and J. and R. Oldfield.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

COLOUR CINEMATOGRAPHY. No. 117,854 (Oct. 19, 1917).—The invention relates to the making of a film in which images of different colours alternate, the alternate tints being produced by masking one set whilst dyeing the other. The full details contained in the specification were published in "Colour Photography" Supplement of January 3 last.—Leon Forrest Douglass, 603, Petahuna Avenue, San Rafael, County Marcia, California.

DECIMAL V. OCTAVAL COINAGE.—In these days of reconstruction the advocates of reform in our coinage and weights and measures are very busy, and in particular the features of the decimal system are the subjects of profuse propaganda. It is, therefore, interesting to receive from our old friend Mr. Alfred Watkins, of Hereford, a pamphlet, in which he not merely urges a case against decimals but pleads for the adoption of an octaval system of subdivision as fitting the wants of those who make, grow, buy, or sell things. Those interested in the question may obtain a copy of the booklet, price 3d., post free, from the Watkins Meter Company, Hereford, or may order it from any bookseller.

New Books.

THE CHEMIST AND DRUGGIST DIARY, 1919.—Our good friends the "Chemist and Druggist" have again given their diary the special form of a highly classified index to the many specialities, mostly proprietary articles, which are sold by druggists. In addition to this feature and to the diary proper, it contains a *résumé* of the regulations affecting the drug trade which have come into force during the course of the war. These literary pages include also particulars up to date of the regulation for the sale of poisons, a war-time formulary, together with other information.

WONDERS OF THE SEA-SHORE.—A volume of nature photography, just issued by Messrs. T. C. and E. C. Jack, price 3s. 6d. nett, consists of 100 reproductions of photographs by Mr. F. Martin Duncan of animals and plants of the sea-shore. Each photograph is supplemented by a few words of description sufficient to explain the habits or functions of the subject of the photograph. A book of this kind is certain to find many interested students among lovers of marine life, to whom the excellent quality of Mr. Martin Duncan's photographs will immediately commend itself.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SUNDAY, JANUARY 12.

United Stereoscopic Society. "Demonstration on Enlarging." J. J. W. Carruthers.

MONDAY, JANUARY 13.

Bradford Photographic Society. Print night: Exhibition of Yorkshire Photographic Union Prints and Members' Prints.

Dewshury Photographic Society. Y.P.U. Members' Lantern Slides.

TUESDAY, JANUARY 14.

Royal Photographic Society. "An Estimate of the Work Done by Hurter and Driffield." J. W. Gordon, K.C.

Halifax Scientific Society (Photographic Section). "Intensification and Reduction without Chemicals." C. Thomas.

Hackney Photographic Society. "Control in Bromoil." G. B. Clifton.

Manchester Amateur Photographic Society. Monthly meeting. "The Life-History of the Wyc Salmon." J. A. Hutton.

WEDNESDAY, JANUARY 15.

Croydon Camera Club. "More Travellers' Samples." F. Ackroyd.

Ilford Photographic Society. "The Old Roman Wall." Rev. J. H. Mitchell, M.A.

Hull Photographic Society. "Flanders and the Low Countries." J. V. Saunders, M.A.

Dennistown Amateur Photographic Association. "Colour Photography." F. Burns.

THURSDAY, JANUARY 16.

Brighouse Photographic Society. Whist Drive.

Hammer-smith (Hampshire House) Photographic Society. "A Chat on Silver and Silver Salts." F. W. J. Krehn.

Rodley and District Photographic Society. "Bromoil." Mr. Gndill.

Liverpool Amateur Photographic Association. Annual Meeting and Election of Officers.

Chelsea Photographic Society. Lantern Lecture. H. H. Wrench.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, January 7, Mr. G. B. Clifton in the chair.

A demonstration by Messrs. F. W. Kent and T. P. Middleton of a new photographic printing material was given by Mr. Middleton. The material, just being introduced upon the market, is known as Kerotype paper, and consists of photographic paper base waxed by impregnation with paraffin wax, then coated with a special substratum (which is the subject of a patent), and then with bromide or gaslight emulsion. The paper is designed for transfer of the emulsion image to all descriptions of surface, such as paper, wood, metal, and fabrics such as silk or satin. The paper is made of three degrees of speed—namely, slow bromide for contact prints, rapid bromides for enlargements, and gaslight. Its chief recommendation to the professional or amateur photographer is that by the use of a single sensitive material prints of very great variety of tint or surface-texture can be prepared by transfer of the image to plain papers such as are available in even greater variety than those supplied ready-coated with emulsion at the present time by manufacturers. The paper is exposed and developed in exactly the ordinary way. If transferred to its new support by a single-transfer method, the image is, of course, reversed. This disability can be avoided by exposing the paper through the waxed support instead of with the emulsion coating in contact with the negative. A very slight degree of diffusion is introduced by this practice.

Mr. Middleton handed round comparison prints, the difference between which was scarcely discernible. In enlarging, of course, this necessity is dispensed with by placing the negative in the reversed position, whilst film negatives may be printed with the plain side in contact with the emulsion surface of the Kerotype paper. Even if it is preferred not to resort to these expedients, the paper can readily yield unreversed plates by a comparatively simple and easy process of double transfer.

It will thus be understood that the novelty in practice connected with the new paper lies in the operations by which it is transferred to various supports. The image on the developed prints, owing to the semi-transparent nature of the waxed paper on which the emulsion is coated is of a flat and lifeless appearance, and does not attain its full rich vigour and gradation until after transfer.

Mr. Middleton, in the course of a demonstration extending little over an hour, showed the different processes by which the paper is handled, according to the surface on which the image is to be transferred and the choice or otherwise of double transfer.

For single transfer to a plain paper support—probably the process which will be most frequently adopted in the use of the paper—the developed, fixed, and washed print is slightly blotted off between sheets of blotting paper and then dabbed over in quite a random manner with a weak, warm solution of gelatine. The paper and print are then brought into contact by light squeegeeing, placed under pressure for a minute or two, and then hung up to dry. The waxed paper can then be stripped off, leaving the picture upon its new support.

Transfer to semi-porous bodies, such as wood, is made by coating both the print and the surface to which it is to be transferred with a little of the gelatine solution, squeegeeing the two into contact, and stripping away the back support after drying. For transfer to metal and similar surfaces which are quite impervious to liquid, the surface is coated with a gelatine solution made with the minimum quantity of water, and containing as much methylated spirit as can be added without throwing down the gelatine. The wet print is dabbed over with a plain gelatine solution, placed in contact with the metal surface, squeegeed, and again stripped after drying.

Mr. Middleton likewise showed the very simple procedure for transferring the image from the dry print to fabrics, and he also demonstrated the use of a resinoid solution containing rubber, gum dammar, and gum elemi, which, as a means of carrying out certain of the transfer processes, is more convenient and rapid than the use of a gelatine solution.

Double transfer either to paper, wood, metal, or fabric is likewise very easily and quickly carried out with the aid of this resinoid solution, and though the descriptions of manipulation, when set down in cold print, appear to represent the process as involving a great deal of manipulation, it requires to be borne in mind that the demonstration showed all the variations of which the new material is capable, whereas the regular user would naturally confine himself to one or two methods only.

In reply to questions, Mr. Middleton said that the prints should be toned before transfer. He said that transfer to glass for lantern slides or enlarged negatives was not practicable, as the transferred image then disclosed a distinct grain. In reply to an inquiry as to the price of the new paper, Mr. Middleton said that it was the same as that of ordinary bromide paper. "Pre-war," asked someone. "Give us a chance," replied the lecturer, to whom an enthusiastic vote of thanks was accorded.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—At the last meeting, Mr. W. F. Slater in the chair, Mr. F. J. Buckland, a professional photographer, delivered a lecture, illustrated with colour slides, on his experiences in Tasmania.

OFFICIAL NAVAL PHOTOGRAPHS.—To facilitate the purchase of copies of official naval photographs in any desired size and style, the Admiralty have arranged with the Associated Illustration Agencies that a copy of every photograph shall be available for inspection by intending purchasers, at the offices of the Associated Illustration Agencies, at St. Mary's Chambers, 161a, Strand (opposite Australia House), and the staff will take particulars of orders and conduct correspondence as to supplying copies of the photographs.

Commercial & Legal Intelligence.

NEW COMPANIES.

ROBERT HAYES, LTD.—This private company was registered on December 27 with a capital of £5,000, in £1 shares, as publishers, publishers' agents, printers, press photographers, etc. The subscribers (each with one share) are:—S. A. Belasco, 61, Fleet Street, E.C., publisher; F. J. Cheringbull, 5, West Grove, Sale, Manchester, publisher; A. A. Ross, 61, Fleet Street, E.C., publisher. First directors:—S. A. Belasco, F. J. Cheringbull, and A. A. Ross. Solicitor:—J. Harle, 61, Tufnell Park Road, Holloway, N.

BOYDE'S STUDIOS, LTD.—This private company was registered on December 31 with a capital of £14,000, in £1 shares (6,000 preferred) to take over the business carried on by A. W. Little, Ada Little, and Electric Studios, Ltd., and to carry on the business of photographers, art dealers, etc. The subscribers (each with one share) are:—Miss F. Hall, 4, Upstall Street, S.E.5; S. A. Pettifer, 32, Langthorne Street, S.W.6, company secretary. First directors:—A. W. Little and H. J. G. Pessers (both permanent). Registered office:—110, Cannon Street, E.C.

News and Notes.

ROYAL PHOTOGRAPHIC SOCIETY.—The following have been elected Fellows of the Society:—W. Foster Brigham, Newman F. Horne, Frederick Humpherson, Lieut. J. H. Jennings, and Floyd Vail.

WAR MUSEUM PHOTOGRAPHS.—The Committee of the Imperial War Museum has taken over the Art and Photographic Sections of the Ministry of Information, and the Photographic Section will now control the official photographs, which are now on sale at 12 Coventry Street.

RAJAH SOCIAL EVENING.—An enjoyable evening of the staff of Messrs. Rajah, Ltd., reinforced by many of their friends, was held at Altrincham on Saturday last, when two plays were performed and a number of musical items presented to the company, after which a programme of dances brought to an end a most pleasant evening.

AN AMATEUR PHOTOGRAPHIC SOCIETY, under the title of the D.S. and S. Camera Club, has been formed by the Liverpool branch of the National Federation of Discharged Soldiers and Sailors, which it is greatly hoped will prove very successful. It is open to all ex-soldiers and sailors, who are cordially invited. The club meets on Thursdays at 7.45 p.m. at the Liverpool branch club house, 154, Islington. All particulars can be obtained from the Hon. Secretary, 19, Wavertree Nook, Wavertree, Liverpool.

ABERDEEN PHOTOGRAPHIC ASSOCIATION.—The sum of £20 15s., representing the total proceeds, without any deductions, of a members' whist drive held just before Christmas, has been handed over to the Aberdeen Red Cross Association by the Treasurer of the Aberdeen Photographic Association. The whist drive was organised and carried out almost entirely by the lady members of the Photographic Association. The Aberdeen Photographic Association has this year brought to Aberdeen the honour of first place in the annual lantern-slide competition held by the Scottish Federation, and also the additional honour of first place in the members' individual competition, the President (Mr. Alfred J. Wood, of Clydesdale Bank) having secured highest marks for a set of three selected slides.

THE LATE MR. FRANK BRUNTON.—We regret to record the death of Air Mechanic Frank Brunton, which occurred at his home, 4, Park Lane, Ighten Hill, Burnley, last week. Although only twenty-eight years of age, he was widely acknowledged as a sincere and gifted worker on the aesthetic side of photography, and as a member of the firm of Messrs. J. R. Brunton and Sons had done much excellent pictorial work, which was far removed from the usual run of commercial photography. Mr. Brunton joined the Royal Air Force in February, 1916, and was attached to the Kite and Balloon Section. During his Army career he had, with characteristic energy,

concentrated his attention to the work in hand, and had passed the requisite tests as an engine fitter. On engine test flights he had spent some fifty hours, covering over seventy ascents, and was reputed to possess unusual nerve and ability. At Lydd, in Kent, where he had been stationed, a wide circle of friends will mourn the loss of a dear friend. He came over on leave early in October, but was soon compelled to visit Dr. Snowball for an ulcer which developed on his eye. Complaining of feeling run down, he took to bed, and after a week passed away at noon last Saturday, the cause of death being attributed to laryngitis and heart failure.

WRITTEN M-FILTERS.—The Wratten Division of Messrs. Kodak, Ltd., have just issued a booklet, entitled "Notes on the Use of Wratten M-Filters," which takes the place of their booklet "Photo-Micrography" now out of print. The booklet is devoted to a discussion of the choice and use of the series of filters which Messrs. Wratten have designed specially for the problems of colour rendering which are encountered chiefly by the photo-micrographer. The booklet contains a useful series of data on exposure, including a table giving the multiplying factor of each filter for a series of artificial light including oil, open-arc, incandescent gas, acetylene, lime-light, and Pointolite, data for the last-named replacing the figures previously given for the Nernst lamp. In addition to the nine filters which form the M set, three others are described as likely to be of use to microscopists. No. 78 converts the light from a metal-filament lamp into daylight as regards spectral composition. It may also be used with the Pointolite lamp, and with half-watt lamps of the smaller ratings. No. 96 D 1.5 is a neutral tint filter, which passes only about 3 per cent. of the light falling on it, and is intended for use when focussing direct with a powerful light-source, or for the purpose of lengthening an exposure which is inconveniently short, as when working at a low power. The third new filter is one of blue colour which transmits no red, and is for visual use where the highest possible resolution is required. The filter is not yet on the market, but inquiries may be made respecting it under the reference No. 38a M. The booklet, which altogether is one which every photographic worker with the microscope should find of constant use, is obtainable from Messrs. Kodak, price 3d.

Correspondence.

. *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

. *We do not undertake responsibility for the opinions expressed by our correspondents.*

THE ASSISTANT QUESTION.

To the Editors.

Gentlemen,—The recent letters on the subject of assistants have been very interesting, and I wonder if any good effect will come of them, or will it all end in smoke? It's a very big problem, that of assistants; and not only that, but too many masters are not as efficient as they might be. They should not be allowed to take apprentices or young people carelessly, to instruct them in methods that are altogether wrong, which unfortunately they do not discover until they make a change of place. Then they discover they have been misled and badly treated. Cannot something be done? Now is the opportunity to reconstruct the whole method of apprenticeship and assistants. Is there not someone strong enough to launch a scheme worthy of our calling? Surely there is an assistant among us with enough pluck to start a union that will be able to assist us to obtain better positions, more money, and better working conditions. Some of the work-places are a disgrace.

We also need more sympathy from our masters. They are helpless without us; therefore, why don't they realise this, and assist us with better opportunities for learning? Some years ago there was a talk about some scheme of examination; what became of it? It's

education, not examination, that matters. In fact, all of us want and would welcome some such scheme.—Yours faithfully,

AN ASSISTANT.

(At present completing three years of service.)

To the Editors.

Gentlemen,—The batch of replies to my last week's letter are very encouraging, and I thank all who have contributed their expressions of appreciation and for the many suggestions made.

I fancy there are still a few who intended sending a line but haven't. It is not too late yet!

Will all those who are interested in this matter assist by talking about it in their work-rooms, and when writing their opinions include the general feeling of their fellow-workers? I here suggest a few questions for consideration.

Do assistants feel they want more help than at present they are receiving?

Do they consider they can command higher wages, or, on the other hand, do they think they are drawing more than they ought through the fact of their not being sufficiently skilled?

Do they understand their work sufficiently, or would they like to have the details explained more fully?

Would they like to become connected with a governing body that would assist them in all matters concerning their efficiency, and thus assist in establishing greater confidence between masters and assistants?

The success of any proposed scheme largely depends upon the attitude shown by the reply letters, so if assistants are really in earnest will they please express themselves? I should like to receive at least 200 letters. We shall then feel impelled to make the effort necessary, and I shall feel more confident in laying the whole matter before the Council of the P.P.A., and it will deserve their most serious consideration.—Awaiting replies, yours sincerely,

MARCUS ADAMS.

The Camera Club, 17, John Street, Adelphi, Strand, W.C.2.

January 6.

AERO-PHOTOGRAPHY AND TOWN-PLANNING.

To the Editors.

Gentlemen,—Very little time has been allowed to elapse between the cessation of aero-mapping expeditions over enemy lines and the putting of the aeroplane and the camera it carries to peace-time work. From the mapping out of the Hindenburg and other lines, with their maze of communication trenches and barbed wire protections, to the air-mapping of rural districts for the purposes of town-planning is, in one sense, but a short step; short as it is, however, it might have taken tape-bound authorities a very long time to take, but the step has been made and the work is about to commence, if, indeed, it has not been carried out already. A builder-photographer states that the Derby Town Council is to be asked to approve an important proposal (included in the new town-planning scheme) for removing three bends in the river Derwent, laying out pleasure grounds adjoining the river, and providing land for new works adjacent thereto. The levels of the land are to be taken in order that the scheme may be properly considered, and in this connection the Air Ministry has agreed, "as a very special case," to take aerial photographs of the town-planning area. This is a new branch of work for the aero-photographers, and one in which there is an immense amount to be done. If the Derby pictures are successful, and are found to be as useful to architects and town-planners as they are expected to be, there surely can be no reason why the hundred and one other places which are to be town-planned should not be "birdseyed" in the same way. The aspect of a town from the air will in time to come be a very important matter, and now is the time to consider the question.—Yours,

AEROPHILE.

THE ALL-ROUND MAN.

To the Editors.

Gentlemen,—It really would appear time someone put in a good word for the despised A.R. man. Specialisation may be all right for one firm in a thousand where an effort is made to produce portraits

(not necessarily good) quite out of the common, for which fancy prices are charged. Men who are only capable of one particular branch of photography are also sufficient for those commercial firms who produce photographs like sausages—negatives at the studios, and retouching, printing, and enlarging at a central workshop. But why a man, instead of becoming, for instance, a retouching machine, should not endeavour to obtain a knowledge, and a thorough knowledge, of operating, printing, and enlarging, etc., as well, is beyond my comprehension.

My experience of thirty years has shown me that the majority of so-called specialists get into a groove from which nothing will move them. As an instance of the value of all-round knowledge, a lady disliked the proof of her little girl taken at a first-class suburban studio. The manageress sent her to the studio for a re-sit. The operator (a new man) asked to see the proof, and found his predecessor had made an excellent negative—posing, lighting, expression were good—so he asked the lady what she disliked, to which she replied, "I like everything but the likeness." The modelling had been spoilt by the retoucher. Had the manageress been competent she would have asked the customer to call next day and submitted a proof with one-third of the retouching, would have pleased the customer, and avoided all the extra work and worry.

In our colonies and similar countries, outside the few large cities, the specialist would starve where the all-round man would attain affluence. The same applies to one-man studios in England. There are cases where photographers have a small business in the provinces and simply make the negatives, which they send to trade houses to be retouched and finished, but the work cannot have the individuality of work commenced and finished by a man with his heart in his work.

A. R. M.

SODA OR POTASH?

To the Editors.

Gentlemen.—Sodium bromide is quite as serviceable as potassium bromide in developers and other photographic solutions, a fact that was pointed out in the pages of the "B.J." some months ago, when the potassium salt was more rare than it is to-day. Many photographers were unaware of the fact until the publication of the note, but they lost no time in trying the sodium salt and finding the truth of the statement. An American journal published in the interests of the drug, oil, and paint trade has made a "great discovery" in connection with the question of sodium versus potassium. An editorial note asks readers of the journal if they ever noticed, in reading a chemical text-book or laboratory manual, that whenever and wherever the use of an alkali is required, the choice invariably falls on potash—e.g., caustic potash? And this being the case, when you come to think of it, did you ever ask yourself why, say, caustic potash is, in the minds of the writers, professors, and "Herr Doktors," so inevitably preferable in all cases to caustic soda? Having asked this, the editor goes on to say that it never occurred to him to ask the question until it was suggested by a friend who is an official in that very-much-alive institution known as the Bureau of Standards. We are told—what some of our readers already claim to know—that the potash "stunt" was German propaganda pure and simple. Potash comes, or did until recently come, out of Germany. German writings have been followed pretty closely by writers on chemistry in all other countries, hence it became a matter of careless habit to write of potassium rather than sodium salts. Our American friend takes up a lot of his news space and uses some forcible language in order to hammer home his remarks. "German propaganda," says he, in conclusion, "pure and simple, nothing more nor less, and very clever and efficient propaganda at that. Salesmanship of the most psychologically complete character. It has caught them all, young and old, wise and foolish. Now, you professors, doctors, and learned gentlemen all, having learned from necessity that caustic soda is just as good, please revise the potassiums out of your books and lectures." From the same journal we learn that there were 30,000 expert chemists in Germany at the outbreak of the war, while France had but 2,500, of which 1,400 were mobilised and 200 of them have fallen in battle. We have, however, no information concerning the casualties among German chemists.—

Yours truly,

NATRIUM

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

J. O. J.—You can get machines for picture-frame making from Messrs. Melhuish, Fetter Lane, London, E.C.

A. F.—We would refer you to an article by "Practicus" in the "B.J." of October 26, 1917, which deals fully with the question of installing artificial light in the studio.

G. D.—A quarter-plate lens, presumably of about 5 in. focal length, is too short a focus for enlarging from a postcard negative. You want an R.R. lens of at least 6 in. focus—better 7 in.

A. J.—Any large plate-glass dealers will supply such slabs. Messrs. J. Hetley and Co., Soho Square, London, W.1, or Alfred Goslett and Co., Charing Cross Road, W.C.2, would quote you.

A. A.—With every desire to help you, we are obliged to say that we know of no method of chemical treatment which is in the least likely to improve ferrotype plates which have slowed with age.

J. A.—Tools for cutting mouldings for frames are sold by Messrs. R. Melhuish, Ltd., 50, Fetter Lane, London, E.C. There is no book on the making of picture frames from the mechanical point of view.

H. W.—It is very difficult to get any lens repairs done just now. We should think your job would be one a watch or clock maker could do. We have succeeded in getting an iris diaphragm repaired in this way, and should think a rotating one should be easy.

C. A. W.—1. We should certainly prefer the 4-plate Sinclair "Una." 2. None better of a folding type. 3. Quite satisfactory for Autochrome work. 4. We do not understand your query; the "Una" camera has been upon the market for a number of years past, and has been successively improved.

J. C.—It is possible to correct the chromatic error in your lens, but it would probably cost much more to do so than to purchase the best lens on the market. Your best course would be to construct a scale showing the amount of racking-in necessary for various distances. Some old lenses have such a scale on the tube.

C. F. S.—The plans you suggest in queries 2 and 3 should answer your purpose best, and with rapid plates you will get the rapidity you require. No blinds are necessary, but a head screen is desirable for local control of the light. There would be much loss by using reflected light, and the lighting would be rather flat.

F. G.—The only reason we can assign is that the formula is too strong—that is to say, there is too much of the Monomet and hydroquinone for the quantity of water. You do not say what your formula is, but from the information you give it would seem that you would avoid your difficulties by taking, say, twice the quantity of water.

M. T.—So far as we know, there is no satisfactory cement for vulcanite. The best way to repair it is to cover the edges with rubber solution, and then to fasten the parts together with strips of vulcanite screwed on with brass screws. The screws must have fine threads, and the holes must be tapped. An electrician could do this for you.

F. M.—Provided the work is first-rate, an average charge is from 7s. 6d. to 10s. per negative, inclusive of one print from each. We should say that whole-plate negatives would be acceptable, although, as it is very usual for such work to be done in 12 by 10 size, you ought to have an understanding with your customer as to what the size is to be. There is no hook on the photography of buildings.

A. T.—The lamp marked on the list is of ample power, but the extended form of filaments is not very suitable, and if we were you we should wait until it is possible to get one of the focus types of lamps of the General Electric Company, which we believe will shortly be again available. These are made specially for projection, and would not require the same amount of diffusion by ground glass in order to avoid filament markings on the projection screen.

A. M.—1. You will get greatly increased illumination by using the 4-in. condenser, as this will be of short focus, and you will utilise nearly all the cone of rays. 2. A 6½-in. lens will give you about the size you require. The diameter depends upon the size of your illuminant. Two inches should be sufficient. Messrs. W. Butcher and Sons list a 6-in. lens complete for 14s., pre-war price. 3. We should much prefer the Telecentric, especially for hand-camera work.

E. V.—The only book on the making of line and half-tone blocks is "Photo-Mechanical Processes," by W. T. Wilkinson, price 4s., from Messrs. Hamptons, Cursitor Street, W.C.2. At a moderate figure the price for a really good working outfit would be from £100 to £150. We ought to say that it would be quite useless your attempting to master this business without practical instruction, such as that from the L.C.C. School, Bolt Court, Fleet Street, E.C., or from Regent Street Polytechnic.

TORN LEATHER.—I have a changing box with leather bag of usual pattern. The latter, unfortunately, got perforated a short time ago by the sharp corner of a plate. Can you tell me the best way to repair the same?—MEDICO.

We know of no method of repairing a cut in leather which we would trust for such an essential matter as the flexible covering of a changing box. We should certainly advise having the leather bag replaced by new.

H. S.—We have not found any solution which will keep the joints of a wooden sink watertight. We have made a sink on the lines you suggest, and have lined it with Rubberoid without a seam. This is a black asphalt-like substance, sold in rolls, and can be obtained from builders' materials dealers. We have also used Trinidad roofing, which is very similar; both are quite satisfactory. Messrs. Kodak, Limited, make dishes on this principle. You might get one as a guide.

H. S.—Your proposed studio is very small and really too low, except for heads and sitting figures. We think that two 1,500 c.p. or three 1,000 c.p. lamps fixed as close to the ceiling as possible would be the best arrangement for it. We should fix galico diffusers below them, and also use the light reflected from the ceiling. We should advise a lens of about 10 in. focal length for work up to half-plate size. If you only wish to do heads you could use up to 14 in. focal length.

W. F. T.—We published an article a few years ago by Mr. Greenfield on the extra-sensitising of plates with dyes, but we do not for a moment think that the results of the formulæ would at all equal the Ilford panchromatic plate, which is made with dyes newly invented. We should advise you to use either these plates or to extra sensitise for yourself with dyes, which you can purchase from Messrs. Ilford. We are unable to say what is the relative gain in speed towards artificial light, but it is very considerable.

NEW BUSINESS.—Will you please tell me if I have to apply for permission to open a new business, or, if, owing to present circumstances, the law has lapsed?—B.

We have not heard that the regulation in regard to the opening of a new retail business has yet been relaxed, although it may not always be rigidly enforced. But we think it would be as well for you to make inquiries from the Director of National Service, at Harewood Barracks, Leeds, addressing your inquiry c.o. Assistant Director of Recruiting.

C. V.—The distances of lamps from the sitter or background cannot be given arbitrarily, as much will depend upon the lighting required. As an average, the front row should be about 8 ft. from background, the sitter being placed forward or back as more or less top light is needed. The nearest side light may be opposite the edge of background, and, say, 4 ft. away from it. The background we assume to be movable, so that you can put it aslant if necessary. The lamps may, of course, be in a curve instead of an actual right-angle or L-shape.

C. V.—1. Six 1,000 c.p. lamps are not too many if you wish for short exposures. 2. In a curve or L shape. Have the lamps to raise to 8 ft. and lower to 5 ft. 6 ins. for children or sitting figures. Use a thin head-screen to prevent over-lighting the upper part of figure. 3. A medium grey or greyish green is the best. White gives flat negatives. You can easily use a movable reflector if needed. 4. We have not heard that the Order has been relaxed, although we believe it is not always rigidly enforced. In any case you should apply to the Director of National Service, 82, Westbourne Terrace, Paddington, London, W.

O. W.—1. There is no better developer for negatives which are to be enlarged than the customary metol-hydroquinone formula, or one of the single-solution developers, the best of which is paramidophenol. Azol, of Johnson and Sons, is perhaps, the best developer of this class. 2. An acid fixing bath of any kind will corrode a metal tank. You should use the hardening fixing bath in an earthenware tank. 3. Undoubtedly pyro is the best developer for warm tones on bromide paper by direct development. 4. Yes, substantially Kachin and pyrocatechin are the same thing, though it is possible that Kachin may contain something mixed with the pyrocatechin. 5. We have no experience of the S.S. screen in Autochrome work: for use with orthochromatic plates it has no injurious effect upon the definition of the lens, and we should think it would answer as well with Autochrome plates.

The Summary of contents which usually occupies the lower half of this column will be found at the foot of the page overleaf and will continue to be placed there whilst its regular position is required for notices relating to the forthcoming "B. J. Almanac."

The First of the 15,000.

It is always something of a satisfaction to us to get the first finished copy of the Almanac. We are getting on. At any rate, the binders have a stock of all the "sheets" which make up the book, and, given a chance, will keep busy in placing them within the familiar yellow or green covers. In ordinary times we could depend on their getting out two or three thousand daily; now their daily output is measured in hundreds, and may be reduced to nothing every now and then by peremptory orders to concentrate all their staff on work of military urgency. Nevertheless, we have reasonable hopes that in the early days of next month there will be thousands enough of the 1919 Almanac to fulfil the orders throughout the United Kingdom.

The 1919 Almanac is still a volume of 644 pages. We daresay that many people will prefer it to the issues of over 1,000 pages, which in pre-war times was unique, we believe, among trade publications. Actually its text portion is almost as comprehensive as ever. To all intents and purposes the Almanac continues to be the up-to-date "enquire within upon everything" which has been its character for years past.

Smaller bulk has been conditioned chiefly by the smaller size of advertisements—in part our publishers' own restriction—but the number still provides a survey of the British photographic trade, and our readers can render a real service to this country and to friends in neutral States by sending a copy of the Almanac to tell its tale of British resources. By the withdrawal of censorship regulations the Almanac can be posted direct abroad, but to get a copy it is necessary to order at once from a dealer, as our publishers are unable to book further orders.

EX CATHEDRA.

Over-printed Self-toning Paper.

With some of the more recent batches of self-toning paper we have noticed a lack of uniformity. One batch that we were using lost very considerably in the fixing-bath, with the result that printing had to be carried much deeper in order to ensure the finished print being of the requisite depth and of a good colour. A later batch, upon fixing the first print or two, showed that it was one in which the prints lost very little, and we at first thought that owing to this difference the whole of the untoned and fixed prints (a very large number) were spoiled through the printing being carried too deeply. They were, however, saved in the following way. A bath containing 4 ozs. common salt in 10 of water was made up and the prints previous to fixing were placed in this for about fifteen minutes. Upon transferring to the ordinary fixing-bath they lost a good deal of depth, being reduced to just the right quality. The tone, of course, was modified, being of a cold black, and equal in every way to platinum-toned P.O.P. In fact, it is so satisfactory that many may decide to finish all their self-toning prints in this way instead of in the ordinary sepia that is so common. We wonder that more users of self-toning paper, and especially the collodion emulsions, do not favour this method more, as it yields prints of delightful richness and quality.

Describing Second-hand Goods.

Those who have at any time had occasion to study the second-hand market must have found that many advertisers, both dealers and private individuals, frequently leave much to be desired in describing the goods that are for disposal. Take the case of apparatus with which the general photographer is not very familiar or that of an older pattern not to be found listed in any of the catalogues issued within the last ten years. We recently saw advertised, "A fine half-plate camera by — (naming a maker of a score of years ago), with two slides, no lens." This kind of advertisement, it must be admitted, gives little or no information as to the instrument for disposal, whether it is of single, double, or triple extension, whether it has a turn or tilting table, or a rising front or swing back, details that any practical worker purchasing a camera requires to have for his consideration. An older photographer might know that particular pattern even from the inadequate description given, but a modern worker certainly would not—unless he happened to have catalogues in hand of a score of years back. We have even seen lenses listed by first-class firms with a reputation for second-hand goods from which the aperture, focal length, and other important details were omitted. Advertisers of second-hand photographic

apparatus will do well to put themselves in the position of the buyer when drafting out details of their goods, giving just those full details that they themselves would wish to have; a few words should not be omitted if their inclusion would give fulness to the description. It may be that an advertisement giving full information will be seen by a buyer on the look-out for the particular model of the apparatus described, whereas he would not take the trouble to write to the vendor, if the goods were not fully detailed, for fuller particulars.

* * *

Rubber Stamps.

As a rule a rubber stamp impression upon a mount gives an idea of cheapness, and quite spoils the effect of what might otherwise be an excellent production. This, like many other things, is due to a want of knowledge of the capabilities of our materials. To many people a rubber stamp is oval or circular in form, the type plain black, and the colour of ink violet, and as far as ordinary office work is concerned these conditions are doubtless satisfactory. It is, however, quite possible to employ rubber stamps in such a way that they may be impressed upon the highest class of mount without being distinguished from lithographic or typographic work. In an instance which recently came under our notice a photographer used a steel die of his signature and town for stamping his mounts or prints. From this he had electros made which were used for printing upon mounts in brown ink. Finding the need for occasionally marking odd mounts and enlargements he sent the original die to a rubber stamp maker and received a rubber facsimile with box, pad and brown ink complete. With this outfit it was possible to sign mounts without causing anything unusual in their appearance. We have also seen the well-known square label form of address, "A portrait from the studio of —," reproduced in the same way, the result being quite satisfactory. The secret of getting good impressions is to keep the pad and stamp free from dust. An old toothbrush is excellent for keeping the stamp clean, while the pad should be scraped the right way of the material with a blunt knife. When fresh ink is applied it should be well rubbed into the pad and allowed to remain for an hour or so before using. When long narrow stamps have to be used it is a good plan to have a small brass prong projecting from one side of the plate, so as to form two little feet, on which the stamp will stand squarely. These feet also afford a good means of keeping the lettering in correct alignment with the edge of the print.

SUMMARY.

The stereoscope, which has long been displaced as an optical toy, bids fair to come into its own for scientific and technical purposes. In an article we give some suggestions for dealing with difficult subjects. (P. 22.)

A full account of Mr. Dudley Johnston's method of producing various tones on lantern slides by development only, with full formulæ and working details, is given on page 25.

The management of the sitter and his friends, with hints upon child photography, form the subject of an article by "Practicus" on page 23.

The concluding section of the report of the Society of Chemical Industry on photographic materials and processes includes many subjects, among which are various colour processes and cinematography. (P. 27.)

A curious variation in the printing depth of self-toning paper, with details of a method for saving over-printed copies without using any of the ordinary reducers, is noted on page 21.

A hint which may be helpful to those who advertise second-hand apparatus in our columns is given on page 21.

UTILITARIAN STEREOPHOTOGRAPHY.

To the great majority of people the stereoscope is nothing more than a scientific toy or perhaps a rather troublesome means of looking at a number of photographs which have cost more than usual labour to produce. In consequence the instrument has been banished from its place in the drawing-room, and only a few enthusiasts who make their own slides venture to keep it in evidence. We have from time to time urged the claim of stereoscopy to be the one branch of photography with which the draughtsman or painter cannot compete, and, further, we have pointed out the great educational value of such pictures, which are as near faithful renderings of their subjects as it is possible to obtain upon a flat surface. When produced in an additive colour process such as that of F. E. Ives, and shown on a binocular Krömsköp the illusion is almost perfect.

For the moment we are not concerned with the beauty or scientific interest of stereoscopic work so much as with its utility in various branches of science and industry. There are many subjects full of intricate detail lying in several planes which cannot be rendered satisfactorily in a monocular photograph or by the cleverest artist. In the one case we have a plan with a certain amount of shading to represent relief and in the other we get the impression of one person who if not an expert in the subject may omit important data, while if he is an expert may unconsciously emphasize such features as seem important to him. The stereoscope is impartial in such matters, and if the separation of the view-points for the two negatives has been properly adjusted the subject should appear exactly as in nature.

It is not necessary to give a detailed list of subjects suitable for stereoscopy, for once the question is raised any intelligent person will readily perceive in what way he can apply it to further his own work or studies. Recently we were glad to hear that the medical profession has shown considerable interest in this work. Many valuable records have been obtained, but there are still many branches of science and art in which development is possible. For example, crystalline fractures such as those of cast-iron or brass, can be photographed on an enlarged scale, and by a judicious separation of the lenses any desired amount of relief can be obtained. As this question of separation has not always been clearly understood, it may be well to point out that the degree of relief obtained is governed entirely by the separation between the lenses when the exposure is made. If only

How rubber stamp impressions upon mounts and stationery may be robbed of their "cheap" appearance is pointed out on page 22.

A communication to "Assistants' Notes" draws attention to the great disparity in the wages paid by different establishments for the same classes of work, and urges upon employers the necessity of establishing a standard minimum wage for each grade. (P. 29.)

Copyright questions, the value of old lenses, flashlight for studio and other work, lens tests, and half-watt lamps are among the subjects dealt with in "Answers to Correspondents." (P. 32.)

At the Croydon Camera Club, Mr. A. Mackie lectured on early photographic history. An interesting account of the fuel value of mummies for locomotive work was added by the president. (P. 30.)

The practicability of using soda salts in place of those of potash, the supply of platinum for photographic purposes, the question of an assistants' union, and fashions in picture postcards are the subject of correspondence on page 31.

A brief account of a discourse of Mr. J. W. Gordon, K.C., on the work of Hurter and Driffeld, pointing out the distinction between their practical results and theoretical conclusions, is given on page 30.

one lens be used and the exposures made successively, then the separation is the distance the lens has been moved. The distance by which the centres of prints is separated has no effect on the relief but only upon the ease with which they are combined in the stereoscope. Much of the eye strain which many people experienced is due to the separation in this respect being too great.

The error that is most likely to be made is that of using too wide a separation when working at close quarters, as when taking small objects on full or even quarter scale and in portraiture or ethnographical studies. The usual focal length of lenses supplied in pairs for stereoscopic work varies from three to six inches. Occasionally lengths up to eight inches are supplied, but this is unusual, except to special order. Even this is insufficient for close up work, as it will readily be understood that at a working distance of eighteen inches the disparity of the view-points of two lenses with a separation of three inches is very considerable, giving a drawn-out appearance to any projecting details. For example, if we desired to take a stereograph of a lump of sugar, we should obtain quite a false rendering of the crystalline texture, the small crystals being drawn out into needle-like forms. It is, therefore, often desirable to avoid the use of paired lenses, and to make the exposures by successively moving the camera the necessary distance.

It will thus be seen that for stereographs of immobile subjects, the possessor of a small camera needs no additional apparatus. All that is needed is a small board or platform on which the camera can be slid laterally and secured at the proper point. Small devices for this purpose are listed by most of the principal dealers, and can, we believe, still be supplied. An appliance which should prove of great value to the scientific photographer is the double mirror, introduced by Mr. Theodore Brown. In this apparatus two small mirrors are hinged together

like a book so that they may be placed either in one plane or at any angle to each other. When inclined together, be it ever so slightly, a dissimilar view of any object is reflected by each, and if these are photographed with an ordinary single-lens camera we have at one exposure a stereoscopic negative, no central partition or other modification of the apparatus being necessary. Although introduced mainly as a cheap and simple means of making stereo-negatives, the Brown transmitter possesses many great advantages. In the first place the limit as to the diameter of the lens is removed. Thus, rapid portrait lenses or large aperture anastigmats of any desired focal length may be used, and in the case of surgical work the simultaneous exposure minimises the risk of movement. A few experiments will be necessary to find the degree of inclination necessary for various distances, and if the mounting included a graduated arc, such as is fitted to binocular field glasses, this could be registered for future use.

There is one slight drawback to this method of working, and that is the fact that the images are laterally inverted, but for scientific work this would in many cases be of no moment; if it were the prints can be made by a transfer process such as Transferotype or the single transfer carbon process or, if films are used, by printing from the reverse side. By this method the negatives may be of much larger dimensions than is possible with a binocular camera even as large as 15 x 12 being practicable. The prints may then be viewed in the Wheatstone or reflecting stereoscope instead of the Brewster or box-form of instrument. Stereoscopic prints, if not made in the form of transparencies, are best if printed on gelatino-chloride paper, as there is less chance of losing shadow detail than there is with developing papers. The negatives should be thin and fully exposed; what would be called flat in ordinary work where the photographer relies only upon light and shade to give a semblance of relief.

PRACTICUS IN THE STUDIO.

MANAGING THE SITTER.

The first step towards managing your sitter is to have perfect control of your own feelings; no matter what worries or annoyances you have to encounter, do not take them into the studio with you. Man is an imitative animal, and in the great majority of cases unconsciously copies the temperament of those surrounding him in a greater or less degree, according to his own strength of character. Therefore, it is very necessary that the photographer should cultivate a quiet geniality of manner, adapting his degree of freedom of speech and manner to that of his sitters, taking care to avoid an excess of familiarity with those who have an idea of their own importance or a patronising air with those of more modest manners. To put it briefly, the operator must be "all things to all men" (and women), and should bear in mind that "As iron sharpeneth iron so is a man's face brightened by the countenance of his friend."

One person at a time is quite enough to manage, and any friends who accompany the sitter must not be allowed to remain in the studio while the sitting is made. If possible they should be induced to remain in the reception-room, but usually it will not be easy to arrange this, and one at least will be allowed to enter the studio. I have always made a rule of having a screened-off corner with a comfortable chair, to which I escort the friend as soon as I have welcomed the sitter, taking care that the friend cannot peep out and be

seen just as an exposure is being made. There is a good reason for this; it prevents the friend from criticising the pose, seen from a totally different position from the camera, and also prevents conversation, which often results in giggling. With children, it is, of course, necessary that they should be accompanied by an adult, but only one should be allowed. If a mother and nurse come, try to get the mother to retire behind the screen, as the child will usually behave better with the nurse, who will not try to excite it. A whole family party in the studio usually means a resitting after a lot of valuable time and plates have been wasted. Even if a family group has been taken, the members should be shown out if separate sittings of any of the children are required, and it is sometimes politic to ask permission to make a negative or two of a pretty youngster, even if not ordered. The parents feel flattered by the compliment, and go away feeling that the photographer is really a man of taste.

We now come to the practical work of making the portrait, some people call it a "picture," and we should endeavour to make it worthy of both designations. To this end it is necessary to make a rapid survey of the sitter's features and figure, so as to get the best result possible. It is said that Reynolds always wanted to dine with a person before he painted his portrait, so as to get a true impression of his appearance, but the photographer is not so fortunate, for he has only a minute

or two to decide upon his course of action. I will endeavour to indicate a few of the points to be observed. There is not one person in a hundred whose features are even approximately symmetrical, so that it is necessary first to decide which side of the face is to be turned to the light. The nose will often appear quite straight if the head be turned one way, and either aquiline or retroussé if turned the other. As a rule it is advisable to choose the straight side unless other conditions militate, in which case the aid of the retoucher must be sought. With nine people out of ten the left side of the face is the most perfect, so that the studio should be arranged to take negatives with the light falling on the sitter's left hand.

The eyes are usually uneven in size and sometimes in height; the best result can be obtained by having the larger or higher eye nearest to the camera. In cases of a decided squint the abnormal eye should be turned from the camera and brought well into shade, so that it can be more easily corrected in the retouching. If the profile is fairly good, one or two positions of it should be taken when the sitter is afflicted in this way.

If the sitter's neck be short it can be made the most of by lowering the camera considerably, while with a long, scraggy neck the camera should be well raised. The height of the camera has an important effect upon the rendering of the nose. A long nose is shortened and the upper lip well shown with a low camera, while a snub nose and long upper lip is better rendered from a higher position. Tilting the head up or down will give the same effect, but this would interfere with the pose of the head and probably spoil the eyes and forehead. A small, receding forehead should be inclined towards the camera, while the possessor of a massive one may throw the head well back. In both these cases the pose will probably be a natural one to the sitter.

The hands are a constant source of worry, and many photographers now look the difficulty boldly in the face and take bust portraits almost exclusively. If they have to be included in the picture the hands should be made as unobtrusive as possible, and care should be taken not to let them come too far forward, or they will appear larger than they really are. It is usually recommended to use the swing back to bring the hands into focus without stopping down the lens, but this is not a good plan, as it necessarily renders them on a larger scale than the rest of the picture. It is always desirable to use as long focus a lens as possible for sitting figures, so as to minimise distortion of this kind. Of course, some sitters have small hands, and then there is little difficulty in dealing with them. One position is always to be avoided, that of having the fingers interlaced while the hands are lying on the knees. A book or flower may be held so as partly to hide the hands, but this device is rather hackneyed. A long chain or string of beads falling from the neck into the lap often affords an opportunity for a graceful arrangement of the fingers.

Full-length portraits are now rarely taken unless for the express purpose of displaying the dress or uniform. For these the camera should be raised, so that the lens is about level with the breast of the sitter—say, five or six inches below the chin. Care should be taken that the body is well balanced upon the feet, which should not be placed evenly, but one a little before the other; in military terms, the sitter should "stand at ease" and not at "attention." At the risk of being considered old-fashioned I strongly advocate the judicious use of the head-rest for standing figures, as not only are "moves" reduced to a minimum, but it prevents the sitter from dropping into a slouching position. I prefer not to place the rest behind the head, but behind one shoulder.

The rest is also very useful when making dancing poses, as it enables a position to be held with one foot in the air. The ironwork should be painted a fairly light grey, so that it is lost in the background and is easy to work out on the negative. If black or dark green, as usually supplied, it is difficult to get rid of.

Young children present a different set of problems from adult sitters. Their features do not require so much consideration, and the lighting is usually full. The great points are to keep them still and to secure a happy expression. They should not be allowed to curl themselves up with one or both legs drawn up under them, but otherwise they will find their own poses, from which the photographer should make his choice. The great thing is to get the child's confidence as soon as it comes into the studio, and to keep the camera out of evidence as much as possible. To attempt to work with children as one would with adults is to court failure. Many of my best child pictures have been obtained by focussing upon a cushion or similar article, placed where it is intended the child to be, before it came into the studio at all; then the plate was inserted, the slide drawn, and the child coaxed into position in an innocent sort of way. Then the exposure was made, using a rather long release tube or cable, and while the child's attention was otherwise occupied the plate changed and the process repeated. A little table at which the child can stand is an excellent accessory, as if a toy be placed upon it in focus the child will usually go to it of its own accord; if spoken to it will usually look up with a pleased expression, and the exposure is instantly made. I generally find that I can get three sharp negatives out of four exposures when working this way. The "little bird" trick is not a bad one; but there should be no deception, the bird should be forthcoming. I have made hundreds of negatives with the help of a cheap toy, consisting of a small metal bird perched on a bulb which contained a water warbler, worked by a rubber tube. The bird flapped his wings and opened his beak while singing. The plan was to tell the child to look for the bird, and to give a note or two on the warbler, and immediately after the exposure to show the bird in action for a few seconds. It was then hidden and the child told that it would come back if he were good. Alas! a little sitter found it when I was not looking, and effectually ended its career. It was probably of Hun origin, and, I hope, cannot be replaced. However, the idea remains, and it might be possible to make a substitute. It is a good plan to keep a few cheap toys so that a child can take one away with it, especially if a resitting may be necessary, as the child will be willing to pay another visit to a place where toys are given away. Big toys, such as Teddy bears, horses, etc., are a nuisance, and the toy should be used to attract the child's attention and not given to it until the exposure is made. Before I learned this I have had a child march away with it into a dark corner and sit down to play with it, any attempt to entice it out being hopeless. I have said nothing about posing either adults or children, as little useful information can be conveyed by words. By the study of paintings, engravings, and the work of good photographers much can be learned and a general idea of what is graceful and artistic obtained, then when the sitter arrives one is not at a loss for a pose. If there is any characteristic mannerism about the sitter it should be preserved; if a man habitually holds his head on one side it is a mistake to put it straight, as it would be to make a man who stoops slightly stand bolt upright.

PRACTICUS.

NEW COMPANIES.

OXFORD STUDIOS (LONDON), LTD.—This private company was registered on January 3 with a capital of £1,000 in £1 shares. Objects: Photographers, photographic dealers, etc. The subscribers

(each with one share) are:—F. Shaw, 1, Town Hall Parade, Brixton Hill, S.W., photographer; Mrs. M. Shaw, 1, Town Hall Parade, Brixton Hill, S.W. The first directors are F. Shaw and Mrs. M. Shaw. Registered office 1, Town Hall Parade, Brixton Hill, S.W.

PERSONAL PRACTICE IN LANTERN-SLIDE MAKING.

[Although at the time we reported fairly fully the admirable lecture delivered by Mr. Dudley Johnston before the Royal Photographic Society we cannot abstain from reprinting the more extended version which is now issued in the Society's Journal. Here appear the practical methods by which the lecturer secures the quality and nicely adjusted artistic variety in his lecture transparencies.—Eds., "B. J."]

Mr. Dudley Johnston enforced the account of his methods by the exhibition of a very large number of beautiful lantern views. He dealt in the first place with the production of slides of warm tone, and in the second with the process of blue and blue-grey tone slides, which are the characteristic feature of his own lecture sets. This latter process, he said, was not by any means easy, but there was no secret about it. It was all set out in Wratten and Wainwright's handbook (first edition) on "Lantern Slides." He believed that it had been discarded in later editions on the ground of difficulty and uncertainty, but his own experience was that it was a more certain and elastic process than the method of physical development which had been substituted. It was undeniably a somewhat difficult process, and required a long experience to work it with reasonable certainty.

He proposed to discuss the subject from the point of view of the production of a set of lantern-slides for lecture purposes. His idea, in the first place, was to consider the set as a whole, and decide upon a general colour scheme most suited to the subject. It was not necessary that the colour scheme be rigidly adhered to throughout, for that would mean a fatal monotony. But a general colour scheme, with judicious variations, formed a restful combination that was pleasing, whereas a constant succession of unrelated contrasts produced distraction. A strong or even a violent colour contrast might be used with telling effect for the climax, but any departures from the general colour selected should only be for a carefully considered contrast, and then only because the colour chosen presented the picture at least as well as the normal colour would. On the whole, a brown that was not too heavy nor yet too yellow was the most pleasant and generally useful colour.

After showing by means of the lantern how occasionally abnormal effects, such as pyro stain or double toning, could be used to serve a pictorial purpose, Mr. Johnston went on to speak of the selection of the subject. For prints a certain amount of diffusion might be desirable, especially in the unessential details of the picture, but for lantern-slide work the negatives required to be in sharp focus throughout. Development was carried through with due regard to the illuminant that was to be used to make the slides. The negatives were dried face downwards, like the slides also, to avoid catching dust or hairs, and very carefully spotted or retouched with the aid of a magnifying glass, in order to avoid as far as possible the necessity of working on the lantern-slide itself.

For making the slides he used a reducing camera made by Lizars, mounted on a baseboard about 5 feet long, with a revolving negative carrier at one end. The camera had a rising and falling front and a swing back, very useful appliances for adjusting the image and for correcting the perspective of vertical lines, etc., if necessary. The lens was a 6-inch Cooke anastigmat, working at $f/65$. Usually he focussed at full aperture to get the maximum illumination of the image, and then stopped down to $f/16$ to make sure of sharpness. He used Paget slow plates almost entirely, rapid plates only occasionally for black tones. It was best to stick to one make of plate. He found no advantage in "backed" plates. His illuminant was a three-tube mercury vapour lamp, the light being reflected from a white card placed behind

the negative. With this light and average negatives the exposures were:—

Black tones	7 to 10 seconds.
Brown tones	30 to 100 seconds.
Blue-grey tones	1½ to 2 minutes.
Violet tones	10 to 15 minutes.

The developer must be adjusted to the exposure. If warmer tones were desired, not only must the exposure be increased, but a corresponding alteration must be made in the constitution of the developer. Neglect of this led to muddy tones.

In development he formerly used adurol for warm tones; this, he believed, was an improved form of hydroquinone, and free from some of the latter's drawbacks. Whether adurol would be obtainable after the war was a problem; but if not, equally good results were forthcoming with a metol-hydroquinone developer, such as is given with every plate-maker's instructions. An important factor in obtaining satisfactory tones was the temperature. He worked, as a rule, at 70 degrees, and sometimes as high as 75 degrees, but great care was then required as the gelatine became very tender. His plan for keeping the developer at a constant temperature in cold weather was to keep a large basin of warm water on the bench and maintain it at 75 to 80 degrees by adding hot water as required, and in this he put all dishes and measures when not in actual use. The fixing solution and washing water should be of similar temperature to the developer.

His aim was so to adjust exposure, developer, and temperature that he got the first faint but distinct image on the plate in about 60 seconds after pouring on the developer. In that case development would be complete in about five minutes. Density was judged by looking through the slide against the lamp. (He used a yellow safelight, Wratten's O.O, with an extra sheet of yellow paper, as his lamp was 32 c.p.). It was curious to note that the developer improved with use. He did not throw it away at the end of his evening's work, but left it in the measure, and on going to work again in a day or two he threw half the old developer away and made up the bulk with fresh. Thus used, it gave better colours, was more regular in its action, and density was more easily judged.

As to blue-grey and blue tones, all of these in his slides were obtained by development pure and simple, and not by any after-toning. The blue tones obtainable by gold toning were well known, but they had not the variety and subtlety of the developed tones ranging from black through blue and violet to red. After showing by examples how this process lent itself not only to moonlight and strong effects, but also to effects of quite notable delicacy, he proceeded to give an outline of the method. The formula of the developer would be found in the first edition of Wratten and Wainwright's booklet on "Lantern Slides," and he expected it was worked out by Dr. Kenneth Mees. According to the exposure and the proportions of the developer, this would give colours ranging from black through blue to purple and red. Even for the black tones the exposure required was about four times that which was normal for an ordinary developer.

DEVELOPER.

A. Metol	44 grains.
Water	20 ozs.
Anhydrous sodium sulphite	½ oz.
Hydroquinone	22 grains.

B.—Ammonium carbonate	1 oz.
Ammonium bromide	1 oz.
Water	10 ozs.
C.—Thiocarbamide	33 grains.
Ammonium bromide	11 grains.
Water	10 ozs.

TABLE OF MIXTURES AND EXPOSURES.

Tone Required.	Exposure.	Developer.		
		A.	B.	C.
		dr.	dr.	dr.
Blue-black.....	4 times normal ...	6	1½	½
Blue	8	5½	2	½
Violet.....	16	5	2½	½
Red	32	4½	3	½

In working this process, he aimed, as in the case of the brown tones, at an exposure which would ensure the first appearance of the image in 60 seconds, using the developer at 70 degrees. Development should then be complete in five minutes. The great difficulty was to gauge correct density, and the only reliable method was to watch the slide by reflected light in the developing dish and follow carefully the various phases. The first appearance of the image was yellowish, darkening to red, and then becoming bluish-black. As development progressed the whole slide darkened over in a manner that might suggest gross over-exposure or fogging, but this was to be disregarded. Presently the darkest portions began to take a lighter tinge, almost as if reversal was beginning. When they showed a well-pronounced buff colour development had gone far enough.

As to colour, this was mainly determined by the exposure and the composition of the developer, but the negative also seemed to have some subtle influence. Cases arose in which a negative would yield a slide of a particular colour, but no variations of exposure and development would induce it to give a really satisfactory slide of any other colour. The colour of the wet slide was usually quite different from what it would be when it was dry. Generally speaking, a slide which was a good blue when dry was pink when wet, but not invariably. This developer, again, was not at its best when fresh, and he was accustomed to put aside what remained over at the end of an evening's work, and when he next wanted to use it, poured half the developer away and added a little fresh, mixed in the same proportions as before.

Fixing took place in acid hypo, then the slide was well washed, then hardened for two minutes in 5 per cent. formalin solution, washed again for five minutes, and finally put to dry on a rack, face downwards, so as to avoid dust, etc. When dry he tested the slide in the lantern and decided whether any reduction or intensification was advisable. In his experience there were few slides that could not be improved by one or other of these processes, sometimes by both.

For reduction the slide should first be soaked in water for ten minutes or more. Hypo-ferricyanide reducer was the more generally useful form. He kept an old egg-cup into which he poured 1 dram of saturated solution of plain hypo, added two or three drops of 10 per cent. solution of potassium ferricyanide, and filled up with water. The finger tip was by far the most satisfactory means of applying the reducer, but a small sable brush was useful at times. It was wonderful how much could be done by these means with practice.

The intensification of slides was a very simple and certain process with the acid silver intensifier:—

A.—Metol	88 grains.
Citric acid	176 grains.
Glacial acetic acid	1 oz.
Water	20 ozs.

B.—Silver nitrate	1 oz.
Distilled water	10 ozs.

For use: 1 oz. A, 1 dram B.

This formula was well known, and was mentioned in many books on lantern-slides, but he had not anywhere seen a reference to one great and valuable property that it possessed, namely, that of intensifying the slide without altering the colour. Whether the slide were brown, black, or blue, it remained the same colour after being treated. It was necessary to apply the intensifier to the dry slide, and the action should not be continued for more than 70 or 80 seconds. If the requisite density had not been obtained in that time the slide should be washed for fifteen minutes and dried, and the intensification repeated. If the action was continued for more than 1½ minutes, or if the slide was first wetted, this intensifier tended to give a bluish tint. It was, as a matter of fact, a physical developer, and could be used to turn a very weak under-developed slide into a good blue one.

It now remained to put the finishing touches before masking and binding the finished slide. He again put the slide into the lantern and examined the projected image carefully for any defects. If there were scratches or abrasion marks, or if pieces of opaque matter or splinters of glass were embedded in the film, there was practically nothing that could be done, and if they were in the sky portion or any other place where they were noticeable it only remained to make a fresh slide. It was otherwise with clear spots, whether due to air bubbles in development or flaws in the negative, and in examining his own slides on the screen he was careful to locate any such marks.

His method of eliminating these was to place the slide on a retouching desk illuminated by a strong light reflected from a sheet of white paper, and to touch out the spots with a pencil having a very fine needle-like point. The pencils he used were 6 H. or 9 H., and the points were trimmed long and kept sharp on a pad of fine sandpaper such as Winsor and Newton made for the use of artists. A needle mounted in a paint-brush handle made an effective retouching tool, as a prick in the gelatine was sufficiently opaque. It also had the advantage of not constantly requiring to be sharpened. He went over the spot with a gentle pricking action as evenly as possible, guiding the operation with the aid of a powerful reading lens. Viewed by transmitted light the effort might appear to show little result, but when tested in the lantern—which, after all, was the conclusive test—it would probably be found much more effective than was thought.

Before binding the slide, he thoroughly dried both the paper mask and the slide before a gas fire, and took great care to exclude all hairs and particles of dust (which showed a most wonderful affection for the warm film) when attaching the cover glass.

Mr. Dudley Johnston concluded by passing a number of slides through the lantern. Most of the slides were Italian views, and they illustrated the capacity of the thiocarbamide process to give, on the one hand, full rich black tones of really velvety quality, and, on the other, red or reddish purple slides, with every effect in between, including delicate greys and blues.

At the close of his lecture Mr. Dudley Johnston was asked what was the best surface to lay the plate on in order to dry, and said he used wire racks above the mantelpiece, and simply supported the plate face downwards against the wall so that there was plenty of air underneath, and yet any dust settling would go on the back of the plate and not on the face of it. In reply to the chairman, who asked whether he fixed face downwards or upwards in the dish, he replied that he fixed face upwards.

PHOTOGRAPHIC MATERIALS AND PROCESSES.

[We are glad of the opportunity of publishing the second of the annual reports on progress in photographic manufacture which has been issued by the Society of Chemical Industry. The author is again Mr. B. V. Storr, M.Sc., of the Ilford Company, to whom students of the technical and scientific side of photography will feel indebted for his analysis of what has been published and accomplished during the period under review, that is to say, the year 1917. We should point out that the reference "J" which figures frequently in the footnotes is to the "Journal of the Society of Chemical Industry." It will, of course, be noted that the report is one which had been completed some considerable time ago. Apparently it is not possible for the Society to bring these reviews out closer to date, although we should have thought that less than a year might be allowed to elapse before the completion of the reviewed period and the publication of the report.—EDS. "B. J."]

(Continued from page 15.)

Colour Processes and Cinematography.

Three-colour cinematograph methods have been produced in America. The Technicolor¹ process, introduced by a company formed to work the Comstock patents, is a two-colour additive method, the images being superposed on the screen. The taking apparatus is a single lens camera with a special form of grid mirror for division of the light; the projection camera includes as a registering device two refracting plates, one in each beam, and pivoted on axes at right angles. The Prizma² process of the Panchromion Co., based on the patents of Wohl and Mayer and Kelly and Raleigh, uses four overlapping colour filters in the taking camera and in the projection camera has two main filters each with smaller sections of a different colour inserted—an orange-red with magenta segments and a blue-green with blue segments. The full details of the third process³ are not to hand, but it would appear to have been brought out by the Eastman Kodak Co. It uses a two-colour single film positive, with the colours on opposite sides of the same film. The printing is done from a colour selection negative with two alternating acts of pictures, a device of lenses and prisms projecting at the same time images of two consecutive pictures one on either side of the positive, each side of which is stained to prevent action of either light on both films.

A large number of patents have been taken out for various details in connection with colour processes. One of the most interesting is that of Szczezanik and Habrich⁴ for the bleach-out process, applied for in 1913; particulars are given of the dyes and sensitizers used. Gartlgruber⁵ covers a stereoscopic process in which the pairs of pictures are in complementary colours. Henley⁶ has a method of stereo-cinematography, using two taking cameras and two negatives from which a single positive is obtained; a special viewing apparatus is required. Wilkinson,⁷ Jones,⁸ Ives,⁹ Hess,¹⁰ and Fox¹¹ (with Kinemacolor) all use variations of very similar methods of obtaining and combining two or three colours in printing. The Brewster Film Co.¹² uses an adsorbent silver halide, formed by the action of a halogen and a halide such as iodine in potassium iodide. Christensen¹³ extends his method of taking advantage of variations in the porosity of a developed film, to the use of special filling substances in the fixing bath. Thornton¹⁴ has several patents in connection with the printing of positives, including the use of a photo-mechanical printing film and special devices for registering films in printing. Shorrocks¹⁵ has a method of staining in two colours at one operation; a film with two sets of alternating pictures, one of which sets has been bleached, is passed through a bath containing a dye such as rhodamine, which stains the bleached pictures red, and ferricyanide citrate, which stains the unbleached pictures blue-green.

In the making of multicoloured screens Piernan¹⁶ has a process

of weaving coloured transparent threads, Schleussner¹⁷ uses a single layer of particles, coalescence being produced by exposure to a solvent vapour. Kitsee¹⁸ obtains very fine particles by spraying a solution of a colloid into a hardening or coagulating vapour, e.g., gelatin into formalin, and Tarlton¹⁹ gets a two-colour screen by a first coating in one colour of a single layer of particles, coating over this with a stained bichromate film, exposing through the back, and developing, which leaves the interstices filled with the second coating.

Walker²⁰ for the Hess-Ives Corporation, uses a reflecting mirror coated with a dichroic compound such as cosine; there is an appreciable gain in the total amount of available light compared with the normal reflecting mirror which cannot utilise more than 50 per cent. of the two component lights.

Miss Greene,²¹ Hochstetter and Pierson²², and Trivelli²³ have patented various methods of renovating cinema films, the two former by mechanical means, the last by means of a lacquer. Ives²⁴ protects the sensitive surface of the film by a varnish of gum damar, removed before development. Lovejoy,²⁵ for the Eastman Kodak Co., uses a composite base, the parts of which are oppositely electrified by friction, thus avoiding the dangers from this source in the handling of sensitised films. Planchat²⁶ dries cinema film by the pressure obtained by passing it through a column of mercury.

Theoretical and Experimental.

The subject of the nature of the latent image has been approached from several standpoints. Channon²⁷ gives an account of some experiments extending over a period of twenty years, showing the effect of time on the latent image; loss of density and veil are the chief effects; there was also some evidence of photo-retrogression in several of the experiments. Homolka²⁸ discusses the difference between ferricyanide and reducing substances such as ferrocyanide, sulphite, and phenylglycine in their effects when plates containing them are exposed to light. There is no visible action in the one case and a blackening in the others, and Homolka uses this result to support the subbromide and perbromide formation theory. (See also a further paper by Crowther²⁹ on the use of substituted *p*-phenylenediamines.) On the other hand Padoa and Mervini,³⁰ from their work on temperature coefficients, conclude that the formation of a latent image is not due to a decomposition of the order AgCl Ag+Cl.

Several interesting papers on the properties of gelatine and its solutions have appeared. Moeller³¹ gives an account of some experiments showing the laminated structure of gellies and supporting the theory of the fibrillated structure of gelatine. Arisz³² has studied the viscosity of solutions of gelatine in a glycerin-water mixture, and its variation with temperature, concentration, etc. He finds permanent loss of viscosity above 65° C., due to partial hydrolysis.

Below this point the change of viscosity with temperature appears to be dual in nature; there is the change produced merely by alteration of temperature such as is shown by all ordinary liquids, and the change produced by alteration of structure. The latter is, especially at low temperatures, much greater than the former, and occurs much more slowly. There is for any temperature above the setting point an equilibrium viscosity, which is, however, diminished at low temperatures by stirring. The Tyndall effect was also examined and the curves connecting this and temperature, as well as the curves for viscosity, were found to be quite continuous, with no break at the setting point. These results are quite in agreement with some obtained in the Ilford laboratories with aqueous solutions, which showed from a study of viscosity and of melting and setting points that the properties of a jelly, as well as those of a liquid gelatine solution, are dependent on its previous history, and the rate of attaining equilibrium is much decreased with lowering of temperature; observations on an industrial scale have also shown that the same is true of dry gelatine film, the properties of which depend both on the condition of the solution from which it is made and on the conditions of drying. The patent of Ilford, Limited, with Renwick and Storr⁹⁰ for the recovery of silver from weak gelatine emulsions is also of interest in this connection; one of the methods used depends apparently on the interaction between the gelatine network and a colloidal hydroxide formed by the dilution of a metallic salt in a slightly alkaline bath, the reaction not taking place with a perfectly fresh gelatine solution nor above certain limiting temperatures.

Biltz, Bugge, and Mehler⁹¹ have studied the osmotic pressure of various gelatine solutions and arrive at some conclusions as to molecular weight and complexity. They compare also for various gelatines viscosity and gold value (the amount of gelatine solution required to protect a standard colloidal gold solution against precipitation by certain reagents).

Hodgson⁹² has published a paper on the physical properties of plate grains, in which some excellent photomicrographs are given in illustration. There is generally a change of shape and an increase of size of grain on development, though occasionally the shape is retained; cases were also found in which development of a grain started from several nuclei. It would be interesting to know the reasons for his conclusion that the silver halide grains are tetrahedra, for silver bromide and silver iodide are both dimorphous (cubic and hexagonal), the latter being hexagonal at normal temperatures, the former either cubic or hexagonal, in the form of hexagonal or triangular laminae. The "feeler" phenomenon previously observed by Scheffer was noticed only once, and then under such conditions as to suggest an entirely different explanation from that advanced by Scheffer, and having no reference at all to the nature of the latent image. Koch and du Prél,⁹³ in the investigation already mentioned, also made a microscopical examination of silver bromide grains in various photographic plates, and the effect on them of exposure, development, and fixing.

Saegusa,⁹⁴ in some work in the crater of a volcano, obtained reversal which he succeeded in tracing to sulphur dioxide; the effect was only temporary, disappearing if the plates were kept several days. He has examined also the varying effects of different coloured lights⁹⁵ and their combined effects on photographic plates; he does not appear to have found any evidence of the antagonism of different colours.

An important contribution to the general subject of photometry is the paper of Renwick⁹⁶ on tone reproduction. By a careful consideration of the curves of sensitiveness of both plates and papers, he indicates to what extent it is possible to obtain a print having the same gradation as the original, and also the possibilities of compensating for the errors of the negative by the qualities of the printing paper. The general question as to what relationship it is desirable to have between the scale of tones of the original and that of the reproduction, a problem which introduces both

physiological and psychological phenomena, also receives consideration. A number of data are collected and arranged respecting range of vision, degree of visibility, contrast, etc., at varying degrees of luminosity, and their bearing on the subject discussed, along with that of the methods ordinarily adopted by artists.

Bloch⁹⁶ has studied the possible variations which may occur in the values obtained for the H. and D. speed number of a plate with variations in the conditions of experiment. He made exposures both with an intensity scale (wedge-screen) and a time scale (sector wheel), avoiding intermittency error in the latter case by using only one slow revolution of the wheel, which was driven by clockwork. The factors actually required to arrive at the value of $\log i$ are the composition of the developer, the γ (degree of development) reached, the value of q (in Schwarzschild's rule, $I_q t = I_1^q t_1$, for equal densities), the nature of the exposure (time scale or intensity scale) and the actual values of time and intensity. The variation of speed with developer is considerable, out of giving the highest number and glycin the lowest of those examined, and the variation with γ is very marked in some cases, especially with high-speed plates having long under-exposure curves. With such plates it is quite common with normal development (i.e., to a γ of about 1) to obtain a straight-line curve for the whole of a normal range of exposures; if development is carried far enough, however, the normal curve becomes evident. A speed number obtained from the first curve, which more nearly represents the working speed of the plate, is much higher than the true H. and D. speed number obtained from the second curve. One case also is mentioned in which Schwarzschild's rule was not obeyed.

Padoa and Mervini⁹⁷ have determined the temperature coefficients of sensitiveness of various plate emulsions and of citrate paper emulsions for a range of lights of different colours. The former are the same (1.05) for all the colours tested (red, yellow-green, violet, and white), but the latter with white, blue, and ultra-violet light are 1.16, 1.19, and 1.07 respectively.

Hodgson⁹⁷ has made a preliminary investigation into the speeds of plates to X-rays. The subject presents some special difficulties because of the fluctuating and intermittent nature of the radiation as ordinarily produced, and the results obtained were only inter-comparable, no definite standard of exposure being suggested. To avoid the intermittency difficulty the moving-plate exposing device of Jones was used and a steady output of X-rays was obtained by the use of a Coolidge tube. The curves obtained differ from the usual light speed curves in being more hyperbolic in shape, neither straight-line nor over-exposure periods being evident.

Goldberg⁹⁸ has determined the tendency to halation by measurement of the fog produced on a protected part of a plate surrounded by exposed parts, making at the same time a comparison wedge-screen exposure. He has also studied the anti-halation effects of various suggested remedies and confirms the prevalent conception that a coloured film between the sensitive film and support is the most effective. Goldberg (*loc. cit.*) also suggested an improvement in Marten's photometer, replacing the usual powerful lamp by a small glow lamp under the photometer table; the method has been tried in the Ilford laboratories with a decided improvement in the range of the instrument.

Hitchins and Gilbert⁹⁹ give a detailed description of the development thermostat in use in the Ansco Research Laboratory. It is on a comparatively large scale and electrically heated and controlled. The developing vessel is an arrangement of two concentric cylinders, the developer being circulated by means of a pump from inside to outside of the inner cylinder, on the outer face of which the plates are suspended.

Luckiesh¹⁰⁰ suggests the use as a correction filter in spectrographic work of a spectrogram placed in correct position on the plate during exposure. Hodgson and Wilsey¹⁰¹ have calculated the actual density required at any point of such a filter, giving the light intensity and the speed of the plate at that point. The device suffers, however,

SODA v. POTASH SALTS.

To the Editors.

Gentlemen. I was much interested in "Natrium's" letter on the use of sodium salts, which emphasises the advantage of chemical knowledge to the photographer.

I have for many years used the salts of sodium (or other metals) wherever they were cheaper or more convenient than the corresponding salts of potassium, with perfect success.

The physical differences have to be taken into account; for instance, one cannot make so concentrated a solution of carbonate of soda as of carbonate of potash, while the reverse applies to the dichromates. Also with exact formulae due allowance must be made for the difference in atomic weights, but in most cases this is negligible.—Yours faithfully,
F. S. WELLS,

Works Manager to P. G. Hunt and Co.

332, Balham High Road, London, S.W.17.

PLATINUM

To the Editors.

Gentlemen.—In the "British Journal" of January 10, 1919, page 14, the following statement occurs: "The supply of platinum is still too limited for it to be available for photographic purposes."

This is quite untrue, and the statement is calculated to do great injury not only to us but to high class photographers who wish to obtain the highest results, both from the artistic and permanent point of view, which can only be obtained by the use of our papers.

Unfortunately the price is very high, but this does not prevent its use, any more than the high price of platinum stops its use for mounting diamonds in place of the old method of using silver for that purpose.

Those who want the best must pay for the best and nothing else will satisfy them.

In spite of the high price of platinum, we have never ceased to supply our Platinotype paper both to Government departments and others requiring permanent records, and to the best photographers who require not only permanence but the highest artistic results.
Yours truly,

ERNEST HENDERY.

The Platinotype Co., Penge, London, S.E.

THE ASSISTANT QUESTION.

To the Editor.

Gentlemen.—I have been forced to notice the various opinions expressed in the Journal regarding assistants.

The notion of a union of photographic workers seems to me not only advisable but imperative in view of past conditions, which, I am confident, are not looked back upon with any great degree of pleasure. Take the case of a man of my acquaintance, a thoroughly good and clever worker (no thanks to the employer to whom he was apprenticed), who before the war received the princely remuneration of 25s. a week, and was expected to run the whole show, from operating to window cleaning. What an ideal condition to be sure! To my mind it is existing, not living.

Personally, I think that prices should remain high—that is, within the purchasing power of the masses. Then perhaps it will be possible to continue the giving of a fairer and better wage than existed in pre-war days when the transition stage is over.

There should be a body of men consisting of an equal number of masters and workers who should arbitrate in the case of an em-

ployee being dismissed against his desire. The findings of this committee should be binding not only on this question, but on others. A fixed minimum wage is necessary for all skilled workers, who should pass an examination to render themselves eligible for that minimum. Hours of working should also be fixed, and an effort made to better conditions under which a great many have to carry on.

Considering the possibilities of things in general and a union in particular, which should surely lead to the betterment of conditions and a closer relationship between master and worker, I cannot but think that apathy reigns supreme in the ranks of present-day workers, male and female. The motto should be "Up and doing." Don't let this chance slide, for if you do you will never have another. Realise your possibilities and remember that the worker is worthy of his hire.—Yours faithfully,
W. E. B.

THE CULT OF THE MODEST COUNTESSANCE.

To the Editors.

Gentlemen. In a letter which appears on page 19 of last week's "B.J." a correspondent calls attention to the soda versus potash question, and quotes an American editor who asked his readers if they had noticed how potassium salts had been boomed to the advantage of Germany. Probably the majority had not, as there is much that is happening in our midst which passes unnoticed.

The question about the chemicals is interesting enough, but I wonder how many photographers in our own country have noticed a revolutionary move in their own profession during the past year or two. I do not refer to any German propaganda, real or supposed, but to the very quiet disappearance of picture postcard portraits of smiling actresses and professional beauties from the shop windows and market.

Not so very long ago portraits of stage favourites wearing what was known as the "Odol look" and showing rows of pearly teeth were as common as modern O.B.E.s. The fixed inane grins depicted by the camera and sold to us on postcards were legitimate subjects for the pencils and pens of humorous artists and writers, who lost but little time in ridiculing them; but now all has changed.

Who are we to thank for the more happy state of affairs, for the more beautiful and restful poses, and for the cult of the modest countenance? Are the more pleasing poses due to the whirligig of time and fashion, to ridicule on the part of artists, writers, and the public, to the craze of the Thespians of minor importance for imitating their betters, to the good sense and persuasions of photographic operators, or what? Like the American editor your correspondent quotes, I think I have made a "great discovery" concerning the matter.

The change is, in my humble opinion, due to the good sense of the most famous of the postcard beauties of to-day, a lady who has been photographed more times than any of those who have reigned in the past, and I need hardly say that I refer to Miss Gladys Cooper. Recently I examined a collection of portraits of the lady named not one of which pictured her grinning. She invariably chooses the restful and more realistic type of pose, and being the leading and most photographed beauty of to-day, others of her calling who are not so favoured by nature have copied her manner of facing the camera.

All in the postcard portrait trade are, I believe, agreed that the coming of the samer and more pleasing of the poses depicted upon commercial postcard portraits coincided with the entry of Miss Cooper into the ranks of beautiful Englishwomen. But although such a great change has come over the postcard portrait of commerce, I find that very few people—particularly photographers—have noticed it.—Yours truly,
L. T. W.

FORTHCOMING EXHIBITIONS.

February 20 to 22.—Leicester and Leicestershire Photographic Society. Secretary, H. C. Cross, 80, Harrow Road, Leicester.

February 22 to March 8.—Edinburgh Photographic Society. Entries close February 13. Secretary, George Massie, 10, Hart Street, Edinburgh.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

ARTHUR HANDS.—The Tella Camera Co., 1, Southampton Row, London, W.C.1.

VALVE 1. List price, £15; worth now about £4. 2. List price, £9; worth now about £3 10s. 3. List price, £4 5s.; now worth about 30s. each. 4. Now worth about 25s.

11. H.—Under the Act which has been in force since 1912 registration of copyright is no longer necessary. If you have dealings in copyright matters we should think that the handbook "Photographic Copyright," which we have issued embodying the regulations under the Act, would be of value to you.

11. P.—Ever since the 1911 Copyright Act came into force registration of photographs has been no longer necessary in order to obtain copyright in them. As you appear to be unfamiliar with the present copyright regulations the purchase of the little manual which we issue would probably be of advantage to you.

TEXT BOOK.—Will you kindly inform me where I can obtain a work that gives general information—in other words, a book of instruction up to date? For four years I have been under Government employ, and have almost forgotten all I had learned by practical experience prior to the war.—VERONICA.

The best general text-book is "The Science and Practice of Photography," by Chapman Jones, price 6s.

11. A.—Ross Universal No. 2, view size, 10 x 8; group size, 8½ x 6½; diameter of lenses, 2¼ inches; back focus, 10¾ inches; price, £9. The original series of universals were f/6 portrait lenses, very similar to the Dallmeyer D series. The full aperture is about f/6, and the other apertures probably require double the exposure at each step. At the present time they should be worth half-price. We are unable to give date of manufacture.

LENS TEST.—1. I have a Goerz Dagor 1 I lens, f 8, but am not at all satisfied with the definition of my outdoor work generally, and would be pleased to know if I could have it examined and tested at the National Physical Laboratory, and where is the postal address? 2. Can you please tell me if and where I can obtain an electrical apparatus for igniting flash powder without any electric current on the premises?—DEFINITION.

1. The address is Teddington, Surrey. 2. Messrs. Boots sell a small lamp in which the ignition is effected by means of an ordinary pocket flash-lamp battery, which might answer your purpose.

E. G.—In order to light magnesium powder by means of methylated spirit you require to blow the powder through the spirit flame. You cannot ignite the powder by means of spirit flame. If we were you we should abandon the spirit pattern of lamp and employ a self-combustible mixture of magnesium and some chemical such as you can best buy ready made, although you can

with some considerable danger make it for yourself, but it is a rule of ours not to recommend formulæ for the making of flash-powders.

S. D.—Spots on the postcards have the appearance of fixing stains, the result of obstruction of hypo to the film from some cause or other. This latter may be air-bells due to handling too many prints together, or might arise from causes in the paper itself. We should try for a start to make a practice of handling prints very thoroughly in the fixing bath and then passing them through a second bath again with very fully turning over. If the spots still persist when prints are thus treated, we think the matter is one which should be taken up with the makers.

11. M.—We can thoroughly recommend the half-watt lamps as giving the nearest approach to daylight effects that we have seen. The specimens in the booklets do some injustice to the light. By judicious screening you can secure any degree of brilliancy. We have not heard of anyone combining mercury vapour and half-watt lamps. If you instal the latter you will not want to be bothered with the mercury. We have not found a better way of using the mercury vapour tubes than the one you mention. Four to six 1,000 c.p. half-watt lamps are the most generally useful selection, as by so dividing the light you do not need to waste so much in diffusing it.

F. M.—The problem you set is a difficult one. The gaslight is out of the question, as in such close quarters the heat would be terrific. The only thing we can suggest is that you should use an enclosed flashlight so that the smoke could not escape into the studio. You could fix, say, four incandescent burners to focus by, and these would help the exposure a little. Can you arrange a pipe to the open air to carry off the smoke? With regard to the printing box, we would suggest a piece of looking-glass in place of the card. This would practically have the same effect as exposing direct to the burner, and we think you will have sufficiently even illumination if you pick out a bit of good plate; wavy sheet glass is no good, as it will give patches of light.

The British Journal of Photography.

IMPORTANT NOTICE.—Advertisers are requested to notice that the prices printed below represent an

Increased Scale of Charges,

which is now in operation in respect to all line announcements.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind this revised tariff. They will thus save themselves delay in the publication of their announcements.

Net Prepaid Line Advertisements.

Increased Tariff of Charges.

12 words or less	1/-
Extra words	1d. per word.

(No reduction for a series.)

Special Note. Adv'ts under a Box Number.

"Box No." and office address charged as 6 words.
For forwarding replies add ... 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.
Orders to repeat an adv't must be accompanied by the advertisement as previously printed.

Advertisements are not accepted over the telephone.

The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.

Displayed Adv'ts should reach the Publishers Monday morning.

The insertion of an Advertisement in any definite issue cannot be guaranteed.

The Summary of contents which usually occupies the lower half of this column will be found at the foot of the page overleaf and will continue to be placed there whilst its regular position is required for notices relating to the forthcoming "B.J. Almanac."

Demand—and Supply.

YEAR by year, since the dimly distant date of August, 1914, it has been necessary to adjust the production of the Almanac in accordance with the circumstances of the time. A year ago we issued only 15,000 Almanacs; they were all speedily bought. This year no more than this number will be available, and the whole edition has been ordered by the trade distribution firms.

Let there be no mistake; a book such as the Almanac, particularly at its now increased prices of 1s. 6d. and 2s. 6d., is not ordered by dealers for chance sale. There are probably very few copies among the thousands already ordered which are not, in fact, earmarked for somebody or other, that is to say, included in our publisher's large totals because somebody in Santiago or Dudley Port months ago told his dealer to secure it. It is for this reason that we must counsel the reader to place a definite order if he wishes to make sure of the 1919 volume. We have urged this precaution in past years because of many instances of its necessity; it is even more needed in the present instance, when the demand is greater than a year ago.

So the 1919 Almanac will come to its readers with a certificate of merit written, so to speak, in the circumstances of the time. The fact that it is wanted in numbers greater than those available serves to mark its indispensability year by year to those engaged in photography in any way.

EX CATHEDRA.

Dark-Room Lighting.

We recently were in the dark-room of a photographic friend whose amateur experience in electric wiring and battery making had been applied in the provision of what he regarded as luxuries in the way of illumination. We are not so sure but that, for a commercial dark-room, there were little more than the necessities for minimising waste of labour. We should explain that our friend's dark-room, which was of ample size, and had the customary developing bench in one corner, had cupboards the contents of which were clearly seen by means of a little yellow electric bulb worked from a battery and connected to the latter so that the opening of the door completed the electric circuit whilst its closing switched the light off again. In many commercial dark-rooms where from lack of space elsewhere things are kept which are not needed in development operations a device of this kind would often save the time of a second assistant who might be wanting them whilst the dark-room was in use. Naturally enough our friend's room was fitted with two types of lamp, one with the safe-light nearly vertical for the examination of negatives, and another of the horizontal pattern for use in the development of prints. Another fixture, and one which we have regularly used ourselves, is a ceiling light consisting of a fairly large lamp placed a foot or so from the ceiling with its safe-light uppermost. The illumination, after its reflection from the ceiling, provides a weak, but safe, and very comfortable light throughout the room.

Passé-Partouts.

The *passé-partout* method of framing may very reasonably be thought to be one which will retain its popularity—certainly among amateur photographers and, no doubt, among the customers of professionals, to whom, however, it has not been offered as freely as its artistic possibilities warrant. It is sometimes astonishing to us to notice the ugly designs of frames which are shown in the show windows of photographers whose taste, judging from their own work in portraiture, might be thought to be a good deal better. The *passé-partout* with its ready adaptability to the key and colour of the print is particularly fitted for the display of window specimens, and, as we have said, might well be offered to the customers of a studio more than it has been. Perhaps the manufacturers may do something towards further popularising this form of framing; the altogether charming metal edging which for some year or two now has been on the market is one way of overcoming an objection to the *passé-partout*, viz., the impermanence of its paper binding. Messrs. Butcher have done something in the same direction by providing the slender frames, which are practically more or less solid surrounds for *passé-partouts*. More might certainly be done in this way by

providing in one form or another a frame for the passe-partout which need only be of the lightest construction, since any hanging tabs or rings are attached to the back of the passe-partout itself, and the accessory frame thus relieved of any weight

Fastest Fixing.

Among other suggestions which we recently made to a correspondent who sent up a batch of stained paper negatives was that of using a hypo bath of the maximum fixing speed. Where, as in the case of such negatives, the process of fixing cannot be seen by the eye it is more than ordinarily necessary to arrange matters so as to secure complete fixation. As was ascertained some years ago by Mr. Welborne Piper in the course of a lengthy series of experiments, a fixing bath of 40 per cent. strength, that is to say, 8 ozs. dissolved in water to make 20 ozs. of solution, fixes more rapidly than any which is weaker or stronger. Although these experiments were made with a particular emulsion, our own experience with plates of many different makes has shown us that for practical purposes the strength of bath above-mentioned may be taken as that which fixes in the shortest time. Obviously more hypo is required to make up a bath of this strength, but, setting aside loss from sheer carelessness, such as splashing the solution about, there is no reason to believe that a bath of this strength is any less economical in use than one containing, say, only 4 to 6 ozs. in a pint of water. We have yet to find a plate with which a bath of this maximum strength cannot be used. In the case of papers it may easily happen that frilling or blisters may arise from the use of a fixing bath of this strength, although in our experience such effects have been very rare.

An Enlargement Attachment

By those photographers who require to make an enlargement only on comparatively rare occasions the studio camera may be very suitably employed. The addition of a small attachment serves to convert it into an enlarger capable of making a print of the size of the largest plate which the camera will take. The attachment consists simply of a box mounted to slide, by means of a panel, in the grooves which carry the camera lens. The box is provided at one end for the reception of the negative to be enlarged and at the other with an R.R. lens of focus suitable for the purpose. The distance between the diaphragm of the lens and the negative will naturally be adjusted in correspondence with the degree of enlargement

required. For this there is the very simple rule that the distance will be one focal length plus one-half, one-third, one-fourth, according as the enlargement is to be two, three, or four times. Where the studio does not provide a ready outlook to a clear sky for the illumination of the negatives, the necessity of tilting the camera may be avoided by using a reflector in the shape of a mirror, or even a white card placed at an angle of 45° to the plane of the negative. An alternative where electric light is used in the studio may consist simply in placing this reflector, or rather the white card, a few inches below an arc lamp or a half-watt bulb.

RE-SITTINGS.

The question of re-sittings is one which perennially crops up, although we do not think that photographers have so much to complain of in these days as they had a few years ago. Probably the broader style of treatment which is now general has a good deal to do with it, while more intelligent and less mechanical retouching has also had an effect. Still, they are common enough to be reckoned one of the plagues of professional photography, and we have to consider the best way to deal with them.

In the first place, the operator will save himself much heartburning if he can bring himself to realise that the sitter does not usually intend to cast any imputation upon his ability. The old hand knows this, but the young artist is apt to take the return of proofs with perhaps rather a pointed remark or two as a sort of blow in the face, and either to contest the matter or to yield with rather a bad grace. That is quite the wrong thing to do. He should endeavour to see the matter from the sitter's point of view as well as from his own, and to do all that he can to give satisfaction. Personal recommendations are the best possible advertisements for any business, and a dissatisfied client will often be the means of diverting many profitable orders, while the assurance that polite and considerate treatment can always be expected will have the contrary effect. There are few people whose genius is so transcendent that they can afford to be ungracious, not to say rude, so that our advice is to stifle one's feelings and to accept an unpleasant situation with a smile. There are, of course, exceptions to this rule, and if the photographer can see that an attempt is being made to impose upon him there are good grounds for protecting himself against it.

It is not wise to mention the subject or to make any conditions as to re-sittings on any price list or even

SUMMARY.

Re-sittings and the best way to deal with them, with notes on their avoidance, form the subject of an article on page 34.

An article on carben printing by artificial light points out how single transfer prints may be made from non-reversed negatives if an illuminant of small area be used. (P. 35.)

Notes on backgrounds, their significance, construction, and use, with hints on fitting and renovation, are the theme of the "Fratricus" discussion on page 35.

The possibility of improving the class of work done and obtaining better financial results from a given number of orders is dealt with in a paper on page 37.

Some remarkable figures illustrating the magnitude of the photographic work done by the R.A.F. during the last few years of the war are given in a reprinted article on page 39.

A clear exposition of the qualities which are essential in a good negative for photo-litho work will be found on page 39.

An improved method of coating celluloid with emulsion, whereby an even film is secured on a slightly buckled base, is the principal item in Patent News. (P. 44.)

A report of the last meeting of the Edinburgh Society of Professional Photographers appears on page 47. The paper read by Mr. Barrie will be found on page 37.

The affairs of two well-known photographers were before the Bankruptcy Court last week. A report will be found on page 43.

A simple enlargement attachment, which can be made at home and fitted to any large studio or other camera, is described on page 34.

Stains on negatives and prints, lens matters, and the introduction of extra figures into groups are among the subjects dealt with in "Answers to Correspondents." (P. 44.)

The utility of auxiliary non-actinic light for illuminating corners and cupboards in the dark-room is pointed out on page 33.

The passe-partout style of mounting for window specimens and as a saleable line to sitters is commended on page 33.

Rapid fixing is a desideratum in many branches of photography. A certain strength of solution gives the most satisfactory results. (P. 34.)

The education of assistants still forms the staple topic in Correspondence. (P. 43.)

verbally at the time of sitting, as this shows a lack of confidence. If re-sittings are so frequent as to be a serious matter it is a sign that there is something wrong with the work, and a decided attempt should be made to remedy it. In many cases faulty or excessive retouching is to blame, and in others a want of attention to small details in dress or posing. Therefore, in every case it should be ascertained what the fault is before proceeding with the second sitting.

Various plans have been tried for avoiding loss in this way, but most of them are open to objection. One is to make a charge if any alteration is made in the dress or style of hairdressing. This appears fair at first sight, but it puts an unpleasant restraint upon the sitter, who may have good reason for complaint, and who can see that certain modifications would help to secure the desired result. Another method is to charge a moderate fee for the sitting and a set of proofs, after which copies may be ordered at a fixed price each. This has its advantages, but as a rule if the proofs are not quite satisfactory the sitter does not return, but tries another studio, so that it is a question of half a guinea sitting fee and no further order or a two or three guinea order with a possibility of a re-sitting at a cost of two or three plates, with perhaps an additional order at the end. In many studios it is the custom to destroy negatives which are not at once approved of, and if the sitter does not wish this to be done to charge a registration fee of, say, half a crown if they are to be kept. Occasionally a sitter will ask for this to be done, in case the second sitting is no more satisfactory than the first. It may be worth while to adopt this plan, but it seems to us that the fewer conditions imposed in an intimate business like portraiture the better.

After all prevention is better than cure, and every step should be taken to avoid the necessity rather than to remedy it when it comes. In the first place, we must remember that the average sitter has no clear idea of the powers of the retoucher, therefore rough proofs should never be submitted unless the negatives are really good

and require but little work upon them. It is difficult to explain that this can be altered and that can be altered; the sitter is not so sure about it, and presses for a re-sitting which would not have been asked for if the alterations had been made before proofing. We have noticed that those portraitists who do most of the work themselves are less troubled than the large businesses where it is carried on on more or less a factory system.

Another point is that sufficient choice of poses should be offered to the sitter. One of the most successful businesses has been built up on the principle of submitting six proofs for an average order. Some people have called this taking your re-sittings beforehand, but it is eminently sensible not only as helping to avoid a second trial, but because with so many positions to choose from the original order is in very many cases increased so that on the whole the additional outlay brings in a good profit. At the present price of plates this may not be regarded as advisable, but there is a wide margin between six proofs and the two which are often submitted.

Whenever it is possible the granting of a re-sitting should be done by the operator and not by the receptionist. The latter may be an excellent business woman, tactful and obliging, but she has rarely the artistic or technical knowledge which are necessary to decide the point. Moreover, the sitter enters the studio with less diffidence if the question has been settled with the person whom she considers is in fault. It should hardly be necessary to say that no proofs with which the photographer himself is not satisfied should be sent out without remark. In such cases it is well worth offering a re-sitting at once. It may not always be accepted, but if it is the sitter comes back in a pleasant mood, which is decidedly helpful. All this is an old story to those who have spent many years in studio work, but we hope that it will go some way to smooth over a disagreeable side of life to those who are still young at it. In every walk of life we are open to criticism, and photographers should be thankful that they are not politicians whose incompetence we see denounced every time we open a newspaper.

CARBON PRINTING BY ARTIFICIAL LIGHT.

ALTHOUGH many photographers, both professional and amateur, will be familiar with the fact that the printing of carbon tissue can be done conveniently with the stronger sources of artificial light, such as the electric arc and mercury vapour lamp, as well as by daylight, it does not appear to be so well known that by choosing a suitable source of light prints without the usual lateral inversion can be obtained from ordinary glass-plate negatives by the process of single transfer only. A few remarks on the method of obtaining such prints may therefore be of interest to those who have the necessary facilities in their studios or homes.

To obtain the unreversed print the tissue must be placed in contact with the plain glass side of the negative, the latter being placed in the printing frame with the film towards the light. The negative must then be illuminated by a very small but sufficiently actinic source, and care must be taken that as little light as possible, other than the direct rays from the source, falls on the plate during the exposure.

The most convenient and satisfactory illuminant is undoubtedly the comparatively new Edison "Pointolite" lamp. The actual source in this lamp is a small metal ball, the diameter of which is about two millimetres, supported in the centre of a glass bulb some 10 centimetres in diameter. The ball is rendered incandescent by a small electric arc, which is

obtained by placing a second electrode immediately over the ball. The usual rating is 100 candle-power, and the current required about 1.5 amperes. This intense and practically "point" source of light is highly actinic, and forms an ideal illuminant for many optical purposes. In using the lamp for the purpose under consideration it is well to place the negative at one end of a box coated inside with a dead black, and to place the lamp outside the box at the other end. A small rectangular hole is to be provided in this end, so that when the lamp is placed as close as possible to the hole the beam of light which enters the box will just cover the film of the negative. The distance between the centre of the bulb and the negative may be 20 centimetres, or even less. It is clear that a number of negatives may be printed at the same time, the bulb of the lamp being placed for this purpose in the middle of a circular or, say, octagonal box with suitable radial partitions; light reflected from the film of one negative must not be allowed to fall on the others. When six negatives are printed at once the cost of printing may be less than that of the final support used in the double transfer process, and there is, of course, also a considerable saving of time. With negatives of average density the time of exposure required is 40 to 50 minutes. The time may be shortened, if fine definition is not required, by reducing the distance between the negative

and the lamp. It may be added that the "Pointolite" takes so little current that it may be connected to any lamp-holder, special wiring not being required.

A second illuminant which will be found to give satisfactory results is the iron arc, but this can only be used where ordinary arc lights are installed or where the electrical fittings allow the use of a current of 5 or 6 amperes. The advantage of an arc with iron poles instead of the usual carbon poles is that the iron burns away very slowly, so that no "feed" is required. In fact, the lamp in this case may consist simply of two iron rods, 1 or $1\frac{1}{2}$ cm. in thickness, supported in the same vertical line with a space of about 4 mm. between their nearer ends. The poles must be, of course, insulated, and connected to the mains in the same manner as the ordinary arc lamp. The arc is most conveniently "struck" by drawing a third iron rod across the ends of the pole pieces. Once the poles become hot the lamp will run for long periods, sometimes for hours, without requiring attention. If the power is supplied by direct current the upper pole should be made the negative one. It is well to place a tray

containing water below the lamp, as occasionally small pieces of molten iron may fall. As the light is very rich in ultra-violet rays it should not be used except when the eyes are protected by plain glass or ordinary spectacles. With this more powerful source a larger number of prints may be exposed at once, the frames being arranged in a circle, say 50 cm. from the light. At this distance no special screens are necessary, and reflection from surrounding objects is of no account unless they are light-coloured. The exposure required at 50 cm. is about 20 minutes, with a current of 6 amperes.

With the distances quoted above the diameter of the circles of confusion representing the points of the image is about .005 mm., but there is a slight loss of definition which appears to be due to reflection between the front and back surfaces of the negative. The want of sharpness, however, is remarkably slight, and in most cases amounts to no more than a softening of the otherwise hard lines of the picture, an effect which in many subjects is quite pleasing.

S. S. RICHARDSON.

PRACTICUS IN THE STUDIO.

BACKGROUNDS.

THE modern photographer regards the background of a picture in a very different light from his predecessor of twenty, or even ten, years ago. Then it was the custom to use elaborately painted scenes, which were supposed to be more or less suited to the social standing of the sitter. Usually they were highly incongruous, and we often found such combinations as a butcher-boy in a tropical conservatory or a lady in evening dress waiting by the banks of bonnie Loch Lomond. I will remember one enterprising firm who went so far as to have the entrance to Hyde Park accurately reproduced with real posts and rails for church parade sitters, and an interior of one of the salons in Buckingham Palace for court dresses. This sort of thing was borrowed from a certain school of portrait painters who considered it necessary to depict their models in what they considered an appropriate entourage. Fortunately we have changed all that, and the scenic background is rarely used except in the "while-you-wait" studio, where it serves to cover up finger-prints and stress markings—in other words, it has almost entirely "retired into the background." The painter had one reason for introducing scenic effects into his pictures which does not apply to photography, for his subject being fully coloured often called for a foil, a warm-toned curtain, or sometimes even a conflagration, as in some naval or military portraits being used to modify a rubicund complexion, while a delicate sky or light foliage served to enhance the charms of a blonde beauty.

The modern photographer has evidently taken a lesson from stage lighting, in which a concentrated light is often thrown upon the principal character, while the garish colours of the scenery are allowed to remain in semi-obscurity; and this has been all to the good as far as the artistic nature of the result is concerned. Many photographers now confine themselves to plain backgrounds. It is a safe course, although one sometimes feels that a little relief would often be acceptable, especially for half and full length poses. Hence a dark cloud or suggestion of foliage is often useful, as it allows the figure to show more relief by opposing a light portion to the shadow side of the sitter. There is one disadvantage in using this class of background because it is not always possible to bring the light patch into the desired position. This was overcome by a device, little known in this country, which consisted

in having the background made in an endless belt running over two rollers, something like a roller towel, by which the height of any portion of the surface can be adjusted to a nicety. Such a background may carry foliage suggestions, clouds, and plain surfaces in various sections, as the length of 16 ft. affords ample room. Another device for securing gradation was to have the ground made in the form of a shallow saucer, which gave a perfectly natural effect of light and shade just where it was wanted. Such a construction was found in practice to be too unwieldy for general use, and a more convenient way of carrying out the same idea is to have a tall screen made of narrow strips of wood glued to an ordinary plain canvas background of a medium grey tint. This can be placed so as to form a kind of alcove behind the sitter, more or less concavity being given as harder or softer gradation is required, or even be used flat, while when done with it can be rolled up and put in a corner. To make the method of construction quite clear, I will compare it to the roller shutter of a studio dark slide, the wooden slips being, of course, turned away from the sitter.

Tapestries and curtains form effective backgrounds if judiciously used, but neither the pattern nor the folds should be pronounced in character, only enough being shown to break up the flatness of a plain surface.

The illumination of the background has an important effect upon its depth of colour, and much may be done by turning it to or from the light, while the distance it is placed under the drawn blinds gives somewhat similar modification. Thus, to obtain the darkest effect from any given tint of grey, we keep it well back from the sitter and bring the edge nearest the side light as far forward as may be, the reverse being done when a lighter tone is required.

In the case of white backgrounds for "sketch" work it is usually recommended to light these independently by opening the blinds behind the sitter. This is all right in a dull light, but on a bright day the flood of light so projected into the lens is very likely to cause a general fog over the negative. Certainly if the quality of the work is to be considered it is better to secure opacity by Mr. Adamson's method of using red ink and secotone on the back of the negative.* A common error is to paint sketch backgrounds a bluish-white, the idea

* "Sketch Portraiture," "B.J." Office, 16d. post free.

being that a denser deposit will be obtained. This is quite wrong; nothing can be whiter than white; the blue only masks any yellow tint in the distemper, and there is no gain by adding it.

From time to time attempts have been made to print in backgrounds from film negatives interposed between the portrait negative or to put in backgrounds on the back of the glass. These plans are rarely satisfactory, though in some cases excellent results have been obtained. As a rule, however, the general effect is not so good as from a background which has been photographed with the sitter.

The materials used for backgrounds are various. For plain tints Melton cloth is excellent when it can be obtained. Failing this, distemper on canvas or stout sheeting is very suitable. For graduated backgrounds distemper may also be used, but it requires a considerable degree of skill to apply it, so that the necessary softness is obtained, and for this class I therefore prefer flatted oil-colour, which does not alter in depth upon drying, and which can be easily worked and softened while wet. Aerograph work upon a plain grey distemper foundation answers very well, but it takes some time to cover so large a space. The aerograph is also excellent for subduing contrast in scenic backgrounds which are too contrasty. I have also improved such by rubbing on black chalk powder exactly in the same way as in finishing an enlargement, but care must be taken to avoid patchiness if there are decided brush marks on the surface. For small grounds up to 54 in. wide dark green or red serge is very good, and a little light may be introduced by dusting powdered French chalk on where required. This is easily removed with a clothes-brush if the plain surface is again required. If you wish to distemper your own backgrounds it is better to purchase one of the many ready-made distempers or to use the Kalko powders (Vanguard Co.), which are specially prepared for this work. Oil-colours should not be purchased ready mixed; they should be procured "ground in oil" in a stiff paste, and this should be thinned down with turpentine or one of the current "turpentine substitutes."

Lincrusta and Anaglypta are useful for making imitation panelled backgrounds. The latter, being a kind of embossed papier mâché, is the cheaper, but will not stand knocking about so well as the Lincrusta does.

Now that we do not require so many backgrounds the old-fashioned multiple stand should be discarded and the material should be stretched upon light wooden frames fixed upon feet with castors, so that they may be moved about the studio easily and used at either end or diagonally, as may be desired. It is a good plan to have the ends of the studio finished so that they may be used as backgrounds. This has also the excellent effect of preventing the space behind the movable screens being used as a receptacle for lumber. The oak panelling comes in

very well for this, and if the entire end be covered a large group can be accommodated without having to eke out the ordinary-sized ground with curtains, side slips, and other makeshifts.

As a guide to those who are attempting to make or renovate their own backgrounds for the first time, I give the following hints. Do not expect to get an even surface with one coat of distemper. You may do so but, if not, do not be discouraged, apply a second coat rather thinner in consistency. If working on new canvas or sheeting it is a good plan to give a first coat or filling of thin size, or even starch or flour-paste. This prevents the distemper from being sucked into the material, and makes it easier to apply. For oil colour, ordinary glue size is to be preferred. A large paint brush, about three inches across, is easier for the amateur to manage than the orthodox distemper brush, and should always be used for oil. Work quietly, and do not slop on too much colour at once. A good grey can be made by mixing a little Venetian red and blue with the black and white. This looks warmer, and photographs better than black and white alone. Remember that distemper dries many shades darker than it appears when wet; therefore before using your mixed colour try a patch on brown paper and dry it before the fire: you will then know what your background will look like when dry. A very little white will turn black into a light grey. Do not buy black in a dry powder, as it is very difficult to mix; ask for black ground in water. Always strain your distemper through muslin before using, or else you will get streaks which are caused by unmixed particles of colour which break up under the brush.

There is a right and a wrong way of nailing a background on to its frame. The wrong way is to fasten all four corners and then to go round the sides. The right way is to drive a strong tack in the middle of the top edge, then to pull the canvas as tightly as possible and drive another tack in the middle of the bottom; then fasten the two sides in the same way. Having got a straight pull these two ways, begin driving in tacks about one and a-half inches apart towards the corners, always working from the centre. In this way any fulness is drawn out as you go on, and the background will be perfectly flat and free from wrinkles. It is a good plan to fasten a loop handle of iron or brass at each side of the frame; this obviates the necessity of handling the edge of the wood, and keeps the background in much better condition. If the frame is wider than you can stretch, a loop of webbing or cord, about eighteen inches long, should be fastened to one of the handles. Holding this and one handle, you can easily move an eight-foot frame single-handed, although if good castors are fitted it may not be necessary to lift it very often.

PRACTICAL.

A COMMISSION SYSTEM FOR RECEPTIONISTS.

SOME FACTS AND FIGURES ON A METHOD OF INCREASING BUSINESS.

(A Paper read before the Edinburgh Society of Professional Photographers).

The paper which I am about to put before you to-night is not with any idea of abusing that very popular side-line, the post-card, which, as we all know, has given such great pleasure to our soldiers at the Front during the long period of the greatest war the world has ever known; but my object is to endeavour to explain to you how clients for these and other small portraits can, by a little tact and co-operation with your assistants, be persuaded to have a superior and more artistic style which will give greater credit to both yourself and your sitters; and I am sure, now that the war is over and we are all looking for better times, this is a most suitable moment to make every effort to raise the standard of photography in general.

Now, can any of you conscientiously say that you have not at some time or other, when you have been looking round your reception-room and workroom, said to yourself that you do not like to see so much small work about which does not do you credit, knowing your ability to produce superior and more artistic styles, and you wish something could be done to educate the general public to a more high-class article. As at the present time wages and materials are so very high, and are likely to remain so for some time to come, something should be done to meet these extra expenses.

Some time ago a friend of mine told me he was having far more work, but very little more turnover on account of the great

demand for small work, and no doubt some of you have experienced the same. Now, the remedy lies with you and the reception room. For instance, a sitter calls at your studio for a sitting. Most receptionists will say, with their usual stock phrase, "Any particular style?" or "What size would you like?" etc. This naturally gives an opening for the request for the size now so popular—the postcard; and the customer will be shown specimens in the usual way, and will give an order for one dozen at, say, 7s. 6d. or 10s. 6d. (more or less). Now, the customer naturally gives them to friends, and in return, sooner or later, they present one of a similar size, and that represents altogether 144 portraits, likewise your advertisement, and would vary from £4 10s. upwards, according to the price of the article, representing a great amount of work and a very small turnover. So much from the sitter's point of view.

Now, we will take our view of the question: the £ s. d. side, the business point, the main issue. We will now suppose another sitter will patronise a studio which has adopted the following principle. The client wishes to be photographed, and is tactfully shown one of your most lucrative productions, priced, just for the sake of argument, at a guinea and a-half per dozen, without asking or waiting to hear what size is required. We will suppose your customer to say that it is a little more than he or she wishes to pay. Instead of bringing forward smaller work I would suggest him or her having eight copies for one guinea or upwards, and might, if the sitter desires to pay something less, even suggest four copies for 10s. 6d. Now may come the time when your customer might say (which is often the case) that she had never had a successful portrait, and thought of only having a postcard, and if it was good would have a larger size. To me, and also to you, there is nothing like the order being booked; you know the old adage, "A bird in the hand is worth two in the bush." This is the opportunity for your receptionist to use her tact and bring out her business abilities. She will suggest to her customer that in the case of a postcard only one plate would be taken and no proof could be given, whereas for those at one and a-half guineas two or three proofs of different positions would be submitted for selection, and a more satisfactory portrait would be likely, in which case your customer, unless she is looking for something cheap, will, nine times out of twelve, see her position, and in all probability give an order for the dozen, and that represents £1 11s. 6d. or more. And when your customer gives her portrait to her friends it is not likely they will give in return one of inferior value; and if that does not benefit you it will the photographer whom they have been in the habit of patronising, which, totalling up the amount, represents £18 more or less instead of £4 10s. (money circulated). Some of you will ask yourself where these clever and valuable young ladies are to be found in these days of shortage of assistants, what with the Wrens, Waacs, and Wrafs, etc., whose ranks so many have loyally joined. I wish to point out that a method which I myself have adopted does not altogether necessitate years of experience to achieve the object in question, as I am about to

show you. Tact and a congenial manner are the main assets to book an order, so long as you have experienced hands in the background to carry it out. And now I think these few remarks have cracked the shell from which I am about to extract the kernel.

To obtain this valuable end it is necessary for you all to look for aid from your receptionist, who is the first to receive your clients. It is in your power and interest to make her post as lucrative as possible. No doubt some of you will say you are already paying as much as, and in some cases more than, the receptionist is worth. But has it ever occurred to you that a little additional encouragement by way of commission on your better work—say, for instance, on all amounts of a guinea and upwards, or about half-a-guinea, where the principal orders of a business are equivalent to postcards—and which I shall show you presently—will decrease your amount of work and increase your turnover? I wish you to note distinctly that too large a commission is not advisable, since what is most easily earned is often the least appreciated. And you must on no account make any reduction in the present wage; it should be given in addition to it. At the same time, if your receptionist is considerably increasing her salary she is simultaneously improving your business, not only the standard, but the turnover, and I have no doubt that all photographers who are not adopting this method up to now will give it their consideration, and will be agreeably surprised at the result, and nothing will give me greater pleasure than to know that my suggestion has been considered.

I am now about to prove my assertion by giving you a few figures, which represent sixty sitters taken during the time I had a qualified receptionist of many years' standing and from one of the leading studios in the British Isles before I adopted this idea of commission, and a further sixty sitters when I had another receptionist with considerably less experience but who worked on the commission system. The list which I have pleasure in placing before you will explain orders up to two guineas only, not above. The first item represents bookcards, which is a smaller size than postcards, in art covers, with a little sketch finish:—

Without commission:—

Bookcards.	Cabinets.	Panels.
51	6	3

With commission:—

Bookcards.	Cabinets.	Panels.
5	24	31
46 decrease.	18 increase.	28 increase.

I think these figures I have given you will convince you that the method is not a mythical one, and to see whether it had the same effect with other businesses as it had with mine I gave the idea to our friend, Mr. Bambrick, who has also been successful, and that gentleman will have pleasure in giving you an idea of his success during the last month only.

NEWTON BARRIE

PROFESSIONAL SHOW IN MANCHESTER.—The fourteenth annual show of "Everything Photographic" was held at 30, Chapel Street, Salford, Manchester, from January 6 to 17, at the premises of Messrs. Wahlisch, Smith and Co., Ltd. Considering the present abnormal conditions, the attendance of professional photographers from all parts of England and Scotland was distinctly good. A new "Universal" printer was shown, and consists of a well-designed light box for printing bromides, taking negatives from 15 x 12 downwards. By a simple switch five lights can be brought into action for use with gaslight papers, or for printing from a dense negative. The exposing switch is in the form of a footboard, pivoted so that pressure on one side brings on the "pilot" red

light, and on the other side the white light. Arrangements are also made for quick insertion of the vignette. There was also a model of a new strip printer for six, on postcards, with automatic feed and change without the use of springs. The mechanism is extremely simple, and the printer can be easily worked by a one-armed assistant. Both machines are made by the company at their own works in Manchester. The bulk of the exhibits in the four showrooms were backgrounds of the latest designs, furniture and accessories, including many novel patterns suitable for studio and household use, all made by the company in Manchester. There were also daily demonstrations of printing on bromide and gaslight papers.

PHOTOGRAPHY'S WAR WORK.

[The immense part played by aerial photography in the prosecution of the war is naturally realised by photographers, a very large number of whom have been practically engaged in carrying it on. But perhaps the magnitude of the scale is not a matter of common knowledge, and therefore we embrace the opportunity of reprinting from the "Daily Telegraph" of Monday last an article which presumably embodies official figures. It is interesting to find that in the essential matters of cameras and lenses the British forces were better equipped than the German. The fact has recently been the subject of remark as regards lenses, and the writer of the notes printed below describes, it will be noticed, the same superiority in respect to cameras.—Eds. "B. J."]

When hostilities broke out in 1914 aerial photography was still in its primitive and experimental stage. A considerable amount of pioneer work had been done both from balloons and aeroplanes; a small but valuable literature was arising; but the impetus of war was required, with the aid of the immense scientific and technical resources behind the Royal Air Force, to exploit its possibilities. Some idea of the progress made can be gained from the fact that on the Western front alone during the last ten months of war no fewer than 264,605 Royal Air Force negatives were taken in the air over German territory, and the gigantic total of 5,800,000 prints was made from these negatives for the use of the Intelligence Staff.

The most recent types of Royal Air Force cameras are very highly finished pieces of work. The lens itself is shielded in a deep tube which faces vertically downwards, thus preventing direct sunlight falling upon it. At the other end of the camera is a steel chamber, containing the automatic device for changing the plates after each exposure. The entire apparatus is securely fastened to the side of the machine, and is connected by a wire with the observer's seat. The pressure of a lever is sufficient to expose a plate and to bring a new plate into position. The German cameras, as recently exhibited in the Strand, lack many of the exquisite mechanical refinements of the British instrument, particularly the ingenious device by which the plates are automatically changed in the air, without any attention whatever from the pilot. This striking British invention has enabled many excellent and valuable photographs to be taken while the machine itself has been under heavy fire both from the air and the ground.

High-Speed Photography.

Anyone who has tried to take a snapshot from the carriage window of an express train realises the difficulty experienced in obtaining a negative entirely free from movement. The same difficulties are, of course, experienced in taking photographs from the air. A modern aeroplane is really a travelling observation platform moving at from fifty to a hundred miles an hour. As the pace of the machine cannot be altered, the object to be taken must be "snapped" as it slips swiftly by beneath the machine. Aerial photography, is, therefore, high speed photography of a special kind. An aerial photograph is almost always under-exposed, and this calls for exceptional treatment when the plates come to be developed. Apart from this peculiarity, however, it is the definite policy of the Royal Air Force to specialise in very thin negatives. A dense negative takes far too long to print by artificial light. A thin negative enables prints to be made in about three seconds. In this way a trained Royal Air Force photographer can print and develop as many as eighty separate enlargements in the course of an hour.

For this scientific work the Royal Air Force has trained large numbers of highly skilled workers. In the model dark-rooms at the Central School of Aerial Photography every candidate for acceptance as a R.A.F. photographer must first pass a severe test, designed to reveal his suitability or otherwise for the work. He is then given

a month's practical intensive training, particular attention being paid to the processes of development, and to the enlargement of negatives by artificial light. Much importance is attached to the rapidity with which these enlargements can be produced, for the fate of a battle may depend upon the promptness with which large-scale copies of a vital subject can be supplied to the Intelligence Staff. After a further course at a training centre in England, the airman-photographer would proceed to a service squadron overseas, and be assigned to a photographic section working with a reconnaissance flight. Such a "section" usually consists of a technical non-commissioned officer and about seven men, who take in turns the more confined and laborious aspects of the work. One man will "load" the magazines with unexposed plates, another will fix the cameras to the machines prior to flight, and receive them on return; others are detailed for developing, washing, drying, and plotting the negatives. Several men are constantly engaged in the enlarging-room, exposing and developing as many as 100 prints in an hour.

Before an Offensive.

It is during the strenuous days preceding a big offensive that photographic activity rises to its maximum. During the successive big drives made by the British in France during the summer and autumn of last year, the entire field of operations was photographed over and over again. If a new series of enemy trenches were constructed during the night, a R.A.F. reconnaissance squadron would bring home photographic evidence of the fact on the following morning. It was no uncommon thing for as many as 11,000 negatives to be made on the Western front alone during a single week preceding an important advance.

In addition to this vast work of aerial reconnaissance, photography was also extensively used for verifying the results of artillery fire, and for recording the precise effects of bombs dropped from the air. The very striking photographs of Frankfurt, Mannheim, Metz, Sablon, etc., recently published in the Press, were actually taken during the raids upon those towns. Another valuable development was the application of the stereoscope to war intelligence. By taking two photographs of the same object, say an enemy trench system, at an interval of a few seconds, a striking stereoscopic effect is obtained which throws all the ramparts and other elevated portions of the enemy work into high relief. In this way the principal difficulties to be encountered by the attacking party can be foreseen.

Aerial photography is destined to become one of the big new industries of the future. The topographical surveys of to-morrow will be photographic surveys; the school and commercial atlases will be photographic atlases. Exploration, commerce, scientific research must all benefit by an industry which may well grow to very large proportions. In this field of post-war industrial activity, Britain will inevitably take a foremost place, for she already has at her command in Royal Air Force personnel some of the most highly trained specialist photographers in the world.

Photo-Mechanical Notes.

Photo-Litho Negatives.

The making of negatives for litho purpose has become an important branch of modern lithography. The difficulty, however, is to obtain workers that are experts in this direction. Workers who intend specialising in this branch should possess or acquire a knowledge of lithography. They should be good photographers capable of using panchromatic as well as ordinary plates. They should understand the intelligent use of colour screens and be able to handle large-sized wet plates for line and half-tone negatives.

Process half-tone negatives will not answer for lithography, as this type of negative records the original in a lower series of tones, which in the subsequent etching are raised to the tone of the original, this attainment often being aided by fine etching. In lithography no etching nor fine etching, as used in process work, can be employed; pure whites on the original must be represented as such on the negative and the other tones in correct dot formation. When eliminating the dot effect in the whites the middle-tones have a tendency to be raised, but provided the original is one suited for the process, this defect can generally be remedied. Flat or imperfect originals should be worked up by an artist who specialises in this work. This point is more important in lithography than in process engraving, as there is not as much latitude

possible when making negatives for litho as there is for process work; lost gradation cannot be recovered as when etching a half-tone plate.

The following different kinds of negatives are used in photolithography:—

1. Ordinary line negatives for black and white work.
2. Screen and grain negatives of the so-called high-light variety.
3. Continuous tone negatives from drawings, photographs, and coloured originals.

These negatives are for some purposes required to be laterally reversed, and other purposes taken direct.

The following list will show the requirement:—

Negatives for printing direct on metal	Reversed.
Negatives for printing on photo-litho paper and then proofing by offset	Reversed.
Negatives for collotype transfers to stone or metal... ..	Reversed.
Negatives for printing direct on metal and then proofing by offset	Direct.
Negatives for printing on photo-litho paper	Direct.
Negatives for making positives from which etched copper plates are made for transfer purposes	Direct.
Negatives for bromide prints	Direct.

When possible the wet-plate process is to be preferred for making photo-litho negatives, as complete opacity and transparency is easily obtained, and as most of the negatives required are usually of large size it is the cheaper method. Negatives must be free from stain, correctly exposed, and well fixed in fresh fixing solution. Excessive chemical reduction or intensification must be avoided, otherwise fine lines will be thickened and broad lines thinned and the character of the original lost. For good quality work the copper-silver intensification is best, for poster and course work the lead ferricyanide intensification is quite suitable and cheaper than the former. The negatives should be made on good quality glass of the same size, or if possible larger than the metal plate on which it is to be printed. If the negative is smaller the edges are likely to dent the litho plate when being printed in the pressure frame; the correct centring of the image is very important. Dot or grain negatives are obtained by photographing the original through a half-tone or metzograph screen. The selection of the ruling or grain of the screen depends for what purpose the result is to be used. Screens of 50 to 80 for poster work, or metzograph screens 00 or 0; for finer work 80 to 120, or 1 to 2 grain screen. For posters of large size the dot in the middle tones may be $\frac{1}{4}$ of an inch across, therefore it will be necessary to make a coarse screen negative and from this an enlarged positive, which is again enlarged when making the final negative. A suitable negative can sometimes be obtained, if the original is good, or if not, has been properly worked up by slightly increasing the screen distance and giving a full shadow exposure with a medium-sized stop and a high-light exposure with the largest stop possible; if the middle tones are raised, skilful reduction will generally restore them.

Another method recommended is to make the shadow or detail exposure, after which the dark-slide is removed from the camera and the screen taken out, and a piece of glass the same thickness as the screen substituted. The dark-slide is then replaced and an additional exposure made through a small stop; this exposure will fog in the high-lights and eliminate the dot effect. Great care must be exercised when removing the dark-slide and replacing, otherwise the sensitive plate will be shifted. Another popular method is to make a bright continuous-tone negative from the original. This negative is then illuminated by transmitted light, and from it is made a screen or grain positive in the camera. If properly exposed the high-lights will be without dot formation and the other tones show correct dot formation; from this screen positive a negative is made by contact or enlargement. The next method is to make a very contrasty-screen negative on a dry-plate; from this is made an enlarged positive by wet-plate. Any dot formation showing in the high-lights can be usually reduced away, and then if necessary the negative intensified. This screen positive can be printed on the metal plate direct by using the Vandyke process, which gives a positive from a positive, and therefore saves making another negative. This way of working is very useful for posters or screen work not exceeding 100 lines to the inch. Continuous tone negatives are used for various purposes in litho-

graphy and chromo-lithography. In chromo-lithography the colour key can be obtained by photographing the original through a suitable colour-screen on a panchromatic plate, it being important that all the detail is shown in the negative. From this negative is made a bromide print or enlargement the size of the production. The print must reproduce all detail without the lower tones being too dense; if too dense the artist will be unable to follow the detail in the tracing made from the bromide print on transparent tracing paper with black ink. The tracing is transferred to stone and proofs taken, which are dusted over with a special dye powder. Offsets are taken from these proofs on the stones used for the colour reproduction, and the artist can then draw in the different colours and detail in register.

Continuous tone negatives are used as a means of obtaining special grain effects, such as for the bitumen grain method, printing direct on the metal through a line or grain-screen in contact with the negative. The negative is sometimes specially treated by fixing or rolling a grain upon it. In the latter direction there are opportunities for experimental work, especially in securing a selective grain in the negative film by chemical or physical means.

The quality of the negative used for these different purposes depends upon the light by which it is to be printed. For daylight printing a good quality thin negative showing all detail; for open arc one showing more contrast; or enclosed arc one showing density coupled with detail. For large poster work, when enlargement is necessary, a lantern slide is made from the negative of the original, and projected to the required size upon a sheet or sheets of transfer paper held in a special frame. On this the artist outlines the detail, thus obtaining the transfer for the key outline. Sometimes large litho proofs are required for special advertising purposes from a set of tri-colour blocks. Proofs are taken of the blocks in good black ink on white enamel paper. From these proofs the enlarged negatives are made by the wet-plate process; the negatives obtained are printed on litho metal and proved in the usual tri-colour inks. Photography can supply the means of linking up lithography and machine gravure, gravure giving the general outline and foundation of the reproduction, lithography supplying the tints or colouring. The time may not be far distant when a gravure and offset machine will be seen running in tandem to secure artistic coloured reproduction of special quality.

It would be worth the process engravers considering the commencement of a special branch to supply lithographers not only with negatives, but transfers on paper, or prints direct on litho metal ready for proving, also suitable bromide prints or enlargements; or any item where photography is necessary, as the process engraver has all the apparatus for carrying out this type of work already at hand.

W. J. SMITH.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, December 23 to January 11:—

TRIMMERS.—No. 21,791. Apparatus for cutting or trimming photographs. J. Merrett and A. Thomas.

CAMERAS.—No. 36 and 37. Photographic cameras. A. and R. S. Ballantine and J. Lizars.

TRIMMERS.—No. 146. Apparatus for cutting or trimming photographic papers. F. Garrett and J. Merrett.

CINEMATOGRAPHY.—No. 209. Cinematograph cameras and projectors. A. H. Oliver.

CINEMATOGRAPHY.—No. 117. Protecting cinematograph films from fire. C. Page.

CINEMATOGRAPHY.—No. 533. Cinematograph projector, shutter, and light-filter. E. R. Alexander and J. O. Wyndham.

COLOUR PHOTOGRAPHY.—No. 420. Method of taking and printing photographs in still life or cinematograph films in natural colours by means only of ordinary camera. W. Finnigan and R. Rodgers.

LANTERN SCREENS.—No. 752. Screens for use with optical projection apparatus. R. J. Fox.

COLOUR CINEMATOGRAPHY.—No. 665. Production of cinematograph colour pictures. A. D. Lacy and T. P. Middleton.

WASHERS.—No. 647. Apparatus for automatically and intermit-

- tently filling with liquid and emptying photographic washers
 F. W. Lawton.
 CINEMATOGRAPHY.—No. 21,842. Stereoscopic cinematograph camera.
 W. Bennett.
 CINEMATOGRAPHY.—No. 21,543. Production of cinematograph films
 by photo-mechanical printing. A. Hamburger.
 CINEMATOGRAPHY.—No. 21,725. Shutters for cinematograph pro-
 jectors. L. Kamm.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from
 the Patent Office, 25, Southampton Buildings, Chancery Lane,
 London, W.C.

The date in brackets is that of application in this country; or
 abroad, in the case of patents granted under the International
 Convention.

EMULSION-COATING OF CELLULOID. No. 121,054 (Mar. 19, 1918).—
 The invention relates to the coating of one side of a film of celluloid
 with emulsion, and has for its primary object to enable the
 coating operation to be carried out in such manner as to ensure
 substantial uniformity in the thickness of the coating notwithstand-
 ing the fact of the film being in a buckled condition prior to the
 operation being carried out.

For the purpose of preventing buckling or curling of the film
 and to keep it perfectly flat and level whilst the coating thereon
 is in a fluid state, it has been proposed to moisten the under sur-
 face of the film whilst passing over a plate after having received
 the coating of emulsion.

According to the present invention the back of the film is
 damped before the application of the emulsion and the film is
 forcibly pressed against a smooth and rigid cylindrical surface to
 which it is caused to remain evenly adherent by atmospheric pres-
 sure during the coating and setting stages of the process so that,
 the buckled portions continuing flattened out during these stages,
 uniformity of thickness in the layer of emulsion is ensured. When
 the now sensitised film is subsequently stripped from the surface
 against which it was adherent, any buckling of the film will not
 affect the uniformity of thickness in the coating.

For the purpose of effecting and maintaining temporary adhesion
 of the film to the smooth and rigid surface against which it is
 pressed, the back of the film, after being damped, is preferably
 rolled down upon the surface so that it remains uniformly and
 closely adherent thereto under atmospheric pressure as a result
 of the expulsion of the air from beneath those buckled portions
 of the film which would otherwise tend to rise from off the surface.
 The sensitised emulsion is applied hot, as usual, so as to be kept
 in a liquid state until the coating has been effected; whilst the
 surface against which the film is pressed is chilled in order to
 hasten the setting of the emulsion. When, after the coating of
 the emulsion has set, the sensitised film is stripped from the sur-
 face to which it was adherent, the back of the film becomes rapidly
 dried on exposure to the atmosphere.

In order that the process may be carried out continuously upon a
 film of considerable length such as is required for cinematographic
 purposes, the unsensitised film, as it is drawn from a spool, is led
 past a device whereby the back of the film is damped, and this
 damped surface of the film is thereupon forcibly pressed into con-
 tact with the periphery of a rotating cylindrical drum by means
 of a spring-loaded roller between which and the drum the film is
 caused to pass, so that, any buckled portions of the film being
 flattened out against the drum, the film remains closely adherent
 thereto under atmospheric pressure until subsequently stripped
 from the drum. Whilst thus flattened and adherent to the drum,
 with which the film is carried round, the film passes between the
 drum and a coating roller whereby a thin layer of emulsion, of uni-
 form thickness, is applied hot to the outer surface of the film; the
 interior of the drum being kept chilled so as to effect the setting
 of the coating of emulsion within a predetermined period of time.
 After the application of the coating, the film is allowed to remain
 in contact with the surface of the rotating drum throughout a part
 of its circumference sufficient to allow the setting of the emulsion
 to take place; whereupon the film is stripped from the drum and
 led to a drying reel.

In the drawing the uncoated celluloid film *a*, initially wound
 upon a spool *b*, is drawn therefrom continuously over guide-rollers
c and *d* to the pressure roller *e* between which and a rotary drum

f of relatively large diameter the film is flattened out. Before
 reaching the pressure-roller *e*, the back of the film *a* passes beneath
 a wick *g* which is kept continuously moistened by contact with
 a rotating roller *h* dipping into a trough *j* containing water; the
 wick *g*, whereof the width corresponds to that of the film itself,
 wiping over the back of the film so as to leave a slight film of
 moisture thereon throughout its entire width. This dampened

surface of the film *a* contacts with the drum *f*, the pressure-roller
e being spring loaded in the direction of the axis of the drum so
 as to exert, against the surface of the drum, sufficient pressure to
 ensure that, as the film passes between the roller *e* and drum *f*,
 it will be forcibly flattened out against the latter, with the result
 that any air imprisoned between the outwardly-buckled portions
 of the film and the surface of the drum will be expelled so that,
 on passing clear of the pressure roller *e*, the film *a* will remain
 closely and solidly adherent to the drum *f* by atmospheric pressure
 alone.

The film *a*, whilst thus adherent to the drum, is carried round
 between the latter and a rotating roller *k* which, dipping into a
 trough *m* containing the emulsion, carries up and applies to the
 outer surface of the film a thin layer of the emulsion the thick-
 ness of which remains uniform owing to the fact that the film *a*
 continues flattened out against the drum. The drum *f* is chilled
 internally so as to cause the coating of emulsion on the film to set
 rapidly, and when the film, as it travels around the axis of the
 drum, reaches the point in the circumference of the latter whereat
 the setting is sufficiently advanced, the film is stripped off and led
 to the drying reel (not shown).

In the example illustrated, the pressure-roller *e* is situated high
 up on that side of the drum *f* at which the film *a* is applied to the
 surface of the drum, whilst the coating-roller *k* is situated low
 down on the opposite side of the drum, and is so driven that its
 periphery moves in the direction opposite to that in which the
 film travels. The surface of the roller *k* should be kept out of
 direct contact with the film *a*, but the emulsion carried up by this
 roller, nevertheless, forms at *o*, just beyond the line whereat the
 roller most closely approaches the film, a "pool" from which
 the film itself carries up with it a layer of emulsion whose thick-
 ness can be adjusted by regulating the distance between the peri-
 phery of the roller and the surface of the film.

The coating roller *k* is so much shorter than the width of the
 film *a* that the layer of emulsion does not extend across the entire
 width of the film, it being desirable that a narrow margin of the
 film should be left uncoated at each side.

The point at which the film *a* is finally stripped from the drum
f is, in the example illustrated, situated near the top of the latter.
 The film, when stripped from the drum, may again become
 buckled, but this will not affect the uniformity of thickness of
 the coating of emulsion.—Newton Livingstone Scott, Lauriston,
 Ashstead, Surrey.

LANTERN SCREENS, No. 121,499 (April 26, 1917).—A coating of
 finely divided particles of mica or quartz is given to the screen
 by employing a suitable size, medium or the like, so that it may

be applied by means of a brush; this greatly increases the quantity of light reflected from the portions illuminated without detracting from the effect of the shadows; it also reduces the amount of light required to illuminate the screen, adds depth and distance effect to the picture, and makes it possible to reproduce on the screen the brilliancy of natural sunshine and other lighting effects.—
 (CHARLES) FREDERICK KIRBY, Oakhurst, 57, Ashbourne Road, Derby

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

- SATURDAY, JANUARY 25.**
 Huddersfield Naturalist and Photographic Society. Lantern Lecture, "Woodsome and its Surroundings." W. H. Sikes.
- MONDAY, JANUARY 27.**
 Bradford Photographic Society. Members' Night: "Transferotype." W. H. Hammond. "Hints and Dodges" by other members.
 City of London and Cripplegate Photographic Society. "The Negative." W. Slater.
 Dewsbury Photographic Society. Lantern Lecture. W. T. Audsley.
- TUESDAY, JANUARY 28.**
 Royal Photographic Society. Presidential Address, Dr. C. Atkin Swan.
 Halifax Scientific Society (Photographic Section). Members Slides. Criticism by members.
 Leith Amateur Photographic Association. Slides due for Lantern Slide Competition. Open meeting.
 Hackney Photographic Society. "The Evening Hour." (Prints.)
 Manchester Amateur Photographic Society. Annual Meeting.
 Chelsea Photographic Society. Demonstration: "Combination Printing." B. C. Wickison.
- WEDNESDAY, JANUARY 29.**
 Croydon Camera Club. Annual General Meeting.
 Ilford Photographic Society. "Highways and Byways of Essex." G. U. Haslam.
 Deunston Amateur Photographic Association. "Hints on Portraiture." W. Foulds.
- THURSDAY, JANUARY 30.**
 Beighouse Photographic Society. Y.P.U. Lantern Slides.
 Hammersmith (Hampshire House) Photographic Society. "Some Leaves from Nature's Book." W. Benington.
 Hull Photographic Society. Kodak "Transferotype" Process, and Ilford "Intona" P.O.P. Demonstration.
 Rodley and District Photographic Society. Members' Night.
 Liverpool Amateur Photographic Association. "Pictures of Egypt." A. Keighley.
 Chelsea Photographic Society. Dark Room.
 Wimbledon Camera Club. A. P. and P. Prize Slides, and Criticism.

CROYDON CAMERA CLUB.

Ma. F. ACKROYD gave a third chapter of "Travellers' Samples" last week, these being lantern-slides from negatives taken on tours at home and abroad. It is not everyone who can rummage through an old stock of negatives and thrice utilise them for chatty lectures, but then everyone is not gifted with Mr. Ackroyd's powers of observation, or possessed of his happy knack of investing even an ordinary subject with humour and interest.

For years he has held an unchallenged position in the club for the production of slides deserving of the highest admiration so far as relates to his wonderful nerve in showing them, and on this occasion, remembering past errors of judgment on the part of his audience, he kindly said that those considered by him to be pictorial would be so notified in advance. This removed much mental strain, and put all in a comfortable state of mind from the start.

In the preliminary canter some slides made from picture-postcards were of interest as showing the deplorable state this industry must have reached. Of interest also were some slides due to a friend who had adopted the novel plan of affixing the indicating discs in the sky—a boon to the lanternist, as the right way up would be seen at a glance. Credit should also be given Mr. Ackroyd (or his friend) for the nice feeling displayed in obliterating pinholes, a monument being erected to each departed.

Half-way through the lecture, when restoratives had vanished under the 9.30 p.m. rules, and all that remained was some non-alcoholic ginger wine which had undergone secondary tetotal reactions imparting a most disturbing flavour, members received a rude shock, for a slide technically and pictorially good suddenly appeared on the screen. After a short pause of petrified astonishment tumultuous applause broke forth, to be renewed when others of the same kind followed. Members who really should have known better got up and warmly congratulated him on the advance made. Advance, indeed! Good slides are not so difficult to produce, but those hitherto characteristic of the lecturer were absolutely unique, plumbing depths unknown to the common ruck, and

it is sad to think such may never be seen again. A most hearty vote of thanks was accorded him for an evening in lighter vein altogether delightful.

EDINBURGH SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

THE fourth meeting of the session was held on Monday, January 13. Mr. Drummond Young, who was in the chair, read a letter from the Secretary of the Edinburgh College of Art intimating that the Board were prepared to meet the retouching class committee of the society to discuss the forming of the class, and arranging for a meeting on the following day, Tuesday, 14th.

The Chairman proposed that a committee might now be formed to investigate the details and costs of a co-operative printing-room on the lines previously discussed, but it was decided that this matter should still be allowed to lie. A committee, however, consisting of the chairman, Mr. George Balmain, and Mr. Johnston, was appointed for the purpose of inquiring into the details necessary for the arrangement of a professional exhibition in Edinburgh.

Mr. Johnston intimated that he had received a sample of plates from the co-operative plate factory, and, so far as he had tried them, had found them quite satisfactory. He promised to report further after having used the remainder.

Mr. Barrie then delivered a paper entitled "Some Facts and Figures on a Method of Increasing Business" (referring to postcard and small work). The paper dealt with a system of giving a small commission to receptionists on all orders booked above a certain value; and he proceeded to show some very interesting figures. Mr. Bambrick warmly approved of the scheme, and quoted his personal experience of it during the previous month, since when, on Mr. Barrie's suggestion, he had adopted the system. A very interesting discussion then followed. Mr. Campbell Harper pointed out that while such a system was of great utility in those businesses where the postcard formed only a part of the turnover, it was scarcely practicable for these firms in which the postcard was the mainstay. He explained that not only was it very difficult to deal with customers individually on busy Saturday afternoons in an endeavour to sell them better styles of work, but that those classes of the community who had limited spending powers would not, and could not, be induced to alter their firm determination to have "postcards" and nothing else. Sympathy was expressed from this point of view, but Mr. Barrie felt sure that, even under such conditions, something might be done by his system.

A point was raised as to whether photographers should supply customers with postcards made from negatives of a cabinet sitting. It was generally felt that this could not be avoided.

Mr. Barrie was heartily thanked for his interesting and instructive address.

It was arranged that at the next meeting a discussion should take place on the fixing of a minimum price for postcards, and it was moved that all Edinburgh photographers should be invited. Arrangements for this summer's holiday closing scheme would be made at the same meeting. The meeting then closed.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—The members were recently conducted over the works of the Realistic Travels, of 73, Warwick Gardens, W. Mr. H. Creighton Beckett, who had extended the invitation, explained in detail, the production of stereoscopic pictures. He demonstrated strip printing and quick development, and stated his record so far as enlarging was concerned is 100 enlargements printed and developed in an hour. One of the most ingenious items was a four-sided print cutter. The prints were passed through, a handle was pulled down, and the print was trimmed all round in one operation. Labour-saving devices were numerous, but these seemed in no way to have had any detrimental effect upon the class of work turned out. In fact, it seemed that the less the pictures were handled the better the final result, and the results were exceptionally fine, both in tone and style. Much of the work turned out by the Realistic Travels bears the stamp, "Crown Copyright," and deals with the war. It is stated that great interest is being taken in the colonies in the stereoscope as a means of education; and certainly the idea is a commendable one, as some of the pictures explain more at a glance than could be conveyed by columns of printed matter.

Commercial & Legal Intelligence.

A PHOTOGRAPHER'S AFFAIRS.—At the London Bankruptcy Court last week, before Mr. Registrar Francke, the public examination was appointed to be held of Harold Aylmer Jones, photographer, lately carrying on business at 30, Hill Street, Richmond; but upon the case being called on for hearing the Official Receiver asked for an adjournment, as debtor had not yet filed his statement of affairs, and he had experienced considerable difficulty in getting him to keep appointments. The debtor formerly carried on business at Richmond under the style of the Castle Studios. He purchased the business for £28 from a Mr. Harwood, paying the purchase money by instalments. He had also carried on business at the South Kensington Studios, 7, Gloucester Terrace, W., but the business was unprofitable, and necessitated his resorting to money-lenders, one of whom sued him and sold him up. He estimated his liabilities at about £300, and alleged his failure to have been caused through loss on trading owing to domestic differences with his wife, who had obtained judgment against him for arrears of maintenance under an order of the Court. The learned Registrar adjourned the examination until February 14, and ordered debtor to file his statement of affairs within a fortnight.

APPLICATION FOR DISCHARGE.—John Page Croft, lately carrying on business at 24, Quadrant Chambers, New Street, Birmingham, made an application for his discharge at the Birmingham County Court, before His Honour Judge Amphlett, on Thursday last. The Official Receiver reported that the receiving order was made in February, 1908. The bankrupt's liabilities were then stated to be £2,323 9s. 8d., and assets were given at £12 10s., but they realised only £1 14s. 3d. In the joint estate of the Page Croft Paper Co., bankrupt's liabilities were £431 12s. 1d., and the assets were stated to be worth £130 3s. 3d., but realised only £36 13s. 3d. No dividend had been paid. The bankrupt, said the Official Receiver, was fifty-six years old, and for ten years prior to the receiving order being made was a tea agent, earning at one time as much as £1,200 a year. For the three years, however, prior to the order his income had been only £200 a year. Bankrupt had lost money by gambling in cycle races, and a tea business with which he was connected was also a failure. He was greatly interested in photography, being a successful exhibitor and a lecturer, and he obtained several considerable sums of money to exploit a new photographic paper, which it was thought would revolutionise photography in this particular direction. This photographic paper business was also a failure, and the Official Receiver described this as a rash and hazardous speculation when bankrupt was already financially involved.

Mr. G. A. Barton, for the applicant, explained that, owing to a rearrangement of the districts, bankrupt's income at one swoop was reduced from £1,200 to about £200 a year. He naturally, therefore, endeavoured to increase his income. He was looked upon as an authority on photography, and his paper experiments were regarded so favourably that he had no difficulty in raising money to make the paper. Unfortunately bankrupt did not meet with success in this enterprise. His position had now slightly improved, and he was earning from £300 to £450 a year. His friends were willing to find a sum of £500 within three weeks to divide among the creditors.—The Official Receiver said he would accept the offer. His Honour, in giving judgment to this effect, said applicant had been unfortunate, no doubt, although somewhat reckless.

THE LATE MR. HARRY J. B. WILLS.—The death has occurred at his residence, 43, St. Helen's Road, Swansea, of Mr. Harry J. B. Wills, who for many years carried on a photographer's business at 22, Morgan Arcade, Cardiff. He is survived by a widow and family.

CO-OPERATIVE PLATE WORKS, LTD.—At an extraordinary general meeting of the Co-operative Plate Works, Ltd., held at the offices of Messrs. E. C. Rawlings, Butt and Howyer, 2, Walbrook, London, E.C., on Wednesday, January 15 last, the following resolution was passed:—"That it has been proved to the satisfaction of this meeting that the society cannot by reason of its liabilities continue its business, and that it is advisable to wind up the same, and accordingly that the society be wound up voluntarily, and that Anthony Bell, of 2, Walbrook, in the City of London, be and he is hereby appointed liquidator for the purposes of such winding up."

EARLY CHAPTERS OF PHOTOGRAPHIC HISTORY.

To the Editors.

Gentlemen,—In his address to the Croydon Camera Club, Mr Mackie omitted to point out that from the consecutive positions of the letters π (Pi) ρ (Rho) in their alphabet, the Greeks evidently knew something of development.—Yours faithfully,

ANNIE MYERS

THE ASSISTANT QUESTION.

To the Editors.

Gentlemen,—I think that an educational governing body for assistants would be very beneficial, and now that Mr. Marcus Adams has so admirably taken up the cudgel, I am sure everyone concerned will consider it a responsibility and voice their opinions.

We know that portrait photography is an art governed by science, and that before art develops technicalities have to be mastered, but I think photography is a profession in which proficiency is reached by laborious shuffling, both by masters and assistants. Apprentices are, in many cases, shamefully treated, because the photographer himself had to "pick it up," and consequently leaves his imitators to do the same. We lack practical art-science education. If an apprentice attends an Art School he is not taught anything practical; drawing from the antique with stumps and chalk does not foster the technique of working upon a photographic surface with a wet point; he is not shown the artistic anatomical draughtsman'ship which governs the process of retouching. Consequently few retouchers have the knowledge of the construction of the head to guide them, but only a vague idea of rounded surfaces with accidental bumps. Hand in hand with a governing body we need an established system of education to facilitate at least some standard of efficiency.

In conducting a class at a Municipal College for professional assistants, I find the students industrious and keen, with feeble encouragement from photographers for them.—Yours faithfully,

GEORGE COLEMAN

The Lodge, Richmond Park Road, Bournemouth.

To the Editors.

Gentlemen,—My sincere thanks to all who have so kindly replied to the assistant question. A few of the letters contain much matter of great interest, but I regret to say I cannot at present find a satisfactory method of dealing with the seriousness of the question. All must admit the loose methods applied at the present moment; in fact, they are almost as impossible as they are unsatisfactory.

Judging from the letters, the assistants blame the masters for the careless way in which they are trained; this, of course, is too true in many cases, fortunately not in all. My personal opinion is that masters ought to stimulate the apprentice and assistant to be always on the look out to pick up information and cultivate the keener desire for education; and until the masters realise their responsibility to the assistant and to the profession of photography the alteration will not take effect.

And I am sorry to say I really believe that many masters don't care, and treat the matter with utter indifference. I can assure my fellow workers that we shall have to face the matter with a determination that will prove satisfactory to the assistants and ourselves, or we shall find ourselves up against difficulties far greater than we see at present. It is to our advantage to organise and form a system without delay.

My suggestion is immediately to compile a complete register of all assistants, with information useful to both parties in case of change of situation, and as far as possible give the record of the assistant.

As soon as this is accomplished the governing body can deal with many important questions, such as the education by post, etc.

Who this governing body shall be is difficult to say; all I feel is the matter is urgent and important.—Yours very sincerely,

MARCUS ADAMS

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

T. A. E.—The Ministry of Munitions. The address was as follows: Director of Optical and Glassware Munitions, 117, Piccadilly, London, W.

W. H.—The address of the glass firm is Messrs. James Hetley and Sons, Soho Square, London, W.1. The cinematograph apparatus firm is now known as the Tyler Film Company, of 13, Gerrard Street, Soho, W.1.

J. H.—Albumenized paper is not now on the market, and your only chance of obtaining it is, perhaps, by advertising. Possibly there are one or two people who have a small stock of the paper they would be ready to dispose of.

W. B.—The bust in question was purchased of Daniele Landi, 36, Charles Street, Hatton Garden, E.C. If you write to him he will doubtless quote a price, including packing and carriage, which will probably exceed the cost of the bust itself, which was 5s. Ask for the head of Gibson's Venus.

A. C.—We cannot assign any reason from the facts stated for the yellow stain. If your water supply is clear and colourless, and remains so on boiling, we do not think it can be the cause. We should say that persistent staining of this kind is a matter which you require to take up with the makers of the paper.

G. S.—We quite think there should be a demand for the dishes treated with your solution. Your best plan would be to make a few samples and submit them, with price per dozen, to some of the larger dealers. We do not much trust any wooden vessel without a lining, as it is easy to start a joint with rough usage.

A. W.—We regret we are unable to answer your queries without further particulars, viz. (1) What class of negatives do you wish to make—landscape, portraits, or copies—and what size plate do you wish to use? (2) What size of miniature, and whether the negatives are to be direct from life or copies? If you will furnish these particulars we will try to advise you.

Miss E. E.—Deep yellow pyro stain is by no means easy to remove. The best advice we can give you is to buy a preparation sold by the Vanguard Company, Maidenhead, and very effective in removing pyro stain. It is compounded from a bleaching powder, but we think you would do better to buy a preparation of this sort ready made than to make it up yourself.

C. E.—Your lens is evidently a cheap rapid rectilinear, and may be of decent quality; it is suitable for nearly all purposes, but rather slow for portraiture. The Planiscope shortens the focal length and includes more subject on the plate. You can use the lens either with or without the Planiscope in the enlarger either for enlarging or reducing. We cannot give the value, but the two are probably worth about 20s. or 25s.

J. B.—We are sorry that we have no list to which we can refer for the Rodenstock lens. As far as we can recollect, it was not cor-

rected for chromatic aberration, and had a sliding adjustment to allow of a correction being made after focussing. We can only advise you to decide by actual trial whether the lens is likely to be of any value in your special work. Certainly do not buy any lens which you cannot have on appro.

L. L.—Retouching is a subject which cannot be taught satisfactorily by means of a book. Some people who have a natural aptness for the work manage to get on with the help of printed or written instructions, but from your letter we should judge that nothing but personal teaching will be of any use to you. We do not propose to deal with retouching in the present Practicus series; even if we inserted diagrams they would be of little value, because so much of the quality of the work is lost in reproduction.

INTRODUCING FIGURE INTO GROUPS.—Could you kindly inform me the best way to insert a photograph of one person in a family group? The family group I have just taken is minus one son, who was killed in the war; hence the request for his photograph to be inserted.—G. S.

It is difficult to give in the limits of a letter working details of the operation you wish to perform. The simplest way is to make an enlargement of the group, then to enlarge the single figure in proportion, cut it out, and paste it on the group, then work up the whole if necessary and make a copy negative the desired size, taking care to avoid a shadow of the cut edge of the figure. This is the plan generally adopted, and you are more likely to make a job than by double printing direct from the two negatives, which requires much practice.

ROYAL PHOTOGRAPHIC SOCIETY.—Dr. C. Atkin Swan's presidential address, arranged for Tuesday last, has been postponed owing to the bereavement in the Royal Family. Dr. Swan will deliver his lecture on Tuesday, the 28th inst., in place of that announced to be given by Mr. E. W. Mellor.

SOCIETY OF MASTER PHOTOGRAPHERS.—A committee meeting of the society will be held at the Manchester Chess Club, 65, Market Street, Manchester, on Tuesday, January 28, at 4 o'clock. Applications for membership should be addressed to the hon. sec., F. Read, 14, Balfour Road, Southport.

The Summary of contents which usually occupies the lower half of this column will be found at the foot of the page overleaf and will continue to be placed there whilst its regular position is required for notices relating to the forthcoming "B.J. Almanac."

Publication.

WE are now at last able to announce the date on which the 1919 Almanac will be on sale. Our publishers tell us that unless something entirely unforeseen occurs to prevent it the books will be obtainable from dealers and booksellers throughout the country who have ordered copies on Thursday, February 6. In London, owing to the large area over which copies have to be delivered, there may, of course, be differences in the time at which the Almanac can be procured. We have not yet arrived at the point at which goods can be deposited at salesmen's doors with ten times the accustomed rapidity from aircraft, but it is possible to say that on Thursday, February 6, the homeward bound Londoner will be able to get his Almanac from his customary dealer. That, of course, supposes that the dealer has ordered copies—and ordered them in time. As has been already pointed out in these notes the distribution of this year's Almanac has perforce been done upon the principle of "first come, first served." Certain dealers have been too late, and, as a consequence, their regular customers must go elsewhere.

And it should also be said for the information of individual purchasers who have not specially ordered copies that by far the greater portion of the edition of the Almanac is now ordered by retailers strictly on the basis of the requests in advance which they receive from their customers, and that therefore the margin which is available for chance sales is very small.

It is therefore necessary to advise the late individual purchaser that he should lose no time, if he wants to get a copy, in applying to his dealer. We hope that by the time the successor to the present Almanac comes to be published it will be unnecessary to devote space in this column to the reiteration of cautions, the necessity of which arises from the limited edition which has been imposed upon our publishers. Of the 1920 Almanac, if events shape as they should, there should be enough and to spare.

EX CATHEDRA.

Ghost Images or Flare. It is a known fact that many of the finest pre-war anastigmats frequently give both ghost images and flare when dealing with subjects which throw a strong light into their glasses. The defect is much less often met when single lenses or the single components of convertible anastigmats or R.R. instruments are employed. "Ghost images" or "flare" are regarded by many photographers as being the more likely with instruments having many glass-to-air surfaces, and as a matter of fact, though not as a general rule, the more of these surfaces there are in the instrument the more likely is the defect to be in evidence in certain classes of work. It is not realised as well as it might be by those who possess anastigmats which exhibit flare or ghost images that much may be done to assist in eliminating these if the instrument is provided with a sufficiently deep hood. We have in our own possession an anastigmat with no less than ten glass-to-air surfaces, and invariably when this lens is used against the light or under like conditions the defects are sure to manifest themselves, yet when the front glass is shaded with a deep and efficient hood we have never had the least reason for complaint. The rarity of ghost images or flare when R.R. or single lenses are used may be traced in part to the fact that with the former class the hoods are much more efficient, as regards the latter, when the single components of the convertible anastigmat are employed it is nearly always the front lens that is removed, and thus the mount of the lens serves as a highly efficient hood for the back glass.

Camera Copies.

The recent installation of the Photostat at the Patent Office brings forward the subject of quick and cheap copying of documents, printed matter, or drawings, by means of the camera. As most of our readers are aware in this and similar apparatus, the print is made by exposing bromide paper in a special camera which is scaled to various sizes. The image is normally a negative one, although positives may be made by recopying them same size. Taken in an ordinary camera the images would be laterally inverted, but this can be obviated by fitting a reversing prism or mirror to the lens, the latter being, of course, much the cheaper arrangement. We think that photographers who work for engineering and other manufacturing firms would do well to take this class of work into consideration, as it would secure many orders for copies of drawings, plans, etc., not amenable to duplication by the usual heliographic methods, which call for a translucent original. It should not be difficult to arrange an attachment to any ordinary large camera for moderate-sized subjects, while larger ones could be managed by taking a small negative and enlarging in the

usual way. We have seen some excellent copies up to three feet across made in this way, and as the work is practically mechanical, highly-skilled labour is not necessary. One point is essential, and that is that the same lens should be used both for making the negative and the enlargement. The operation has been very successfully carried out thus: supposing an architect's drawing has to be reproduced, a copy is made upon a process-plate, say, half-plate or whole-plate size, the distances between lens and original and lens and plate being accurately measured. The lens is then transferred to the enlarger, and the negative and bromide paper carefully placed at exactly the same distances, the result being a full-sized copy free from any distortion, the image having been made to travel back through the same optical system by which it was produced. Where much work has to be done it would be well to have both camera and enlarger rigidly set to the required points so that for full-sized reproductions no setting would be necessary. With a proper artificial lighting scheme the exposures of both plate and enlargement would be a fixed quantity, and a spoiled sheet almost unknown.

* * *

The Shop Window.

A few days ago we were asked whether it was advisable to retain a shop window for the display of specimens or to be satisfied with show-cases in a lobby and let off the shop. This is not quite such a simple question to answer as it appears at first sight, since many factors have to be taken into consideration. The first of these is the class of business which is intended to be done. The highest class of portraitists depend almost entirely upon introductions, and to a lesser degree upon reproductions of their pictures in the press. Some go no farther than a brass door-plate to advertise their locale, a few even dispense with this, while others have modest show-cases with only one or two specimens on view at a time. A few of the older firms have large lobby shows or shop windows, but it is not until we reach those who cater mainly for chance trade that we find the window show really popular. Recently there has been a great increase in these window shows in London and other large centres, so that we must conclude that they have been found to be a paying proposition. It may be noted that many of the large portrait shops are being run by people who are also engaged in other branches of industry, and they have treated photographs in the same way as they would clothes, jewellery, or tobacco. Surely, therefore,

it is quite in order for the photographer, pure and simple, to take a leaf from the business man's book and to go in for bold advertisement, providing that he has the means to do it properly, and not to lose sight of the next important factor in the matter—that of locality. To be effective a window display must be situated where there is a considerable amount of traffic, and in what may be called a shopping or market thoroughfare, where there are other attractions. Even in the same street one position is valuable and another almost worthless. In nearly every important thoroughfare there is one side which is much better for business than the other, and this the keen business man is careful to ascertain before he invests his money.

SOME NOTES ON PRINT-METERS.

Of the many forms of print-meters, or actinometers, the type dependent upon miniature negatives of graduated density is preferred by some, as no matching of tint is required, and for occasional work with only a few frames exposed it certainly is convenient. On the other hand, the most accurate of all probably is the "single-tint" tint-matching type, almost essential when many frames have to be kept going and taken in and out during the day's work, but it requires constant inspection, and if one tint is overdone accidentally only a rough estimate is possible to compensate for the over-printing. Single-tint meters, such as Johnson's, supplied by the Autotype Company, are provided with a roll of P.O.P., which under varying atmospheric conditions does not always make a good match with the surrounding tint, the yellow glass above necessarily being of insufficient depth to remove colour contrast. Greater accuracy in reading is secured by not attempting to effect a colour match, but to work in the following way:—If the nearest edge of the rectangular aperture is viewed obliquely from a fair distance with the eyes partially closed, it will initially stand out lighter than the darkening silver paper beyond it, and at a certain stage will merge into the tint and be lost, which point is taken as "one tint." Tests have shown that this method largely eliminates the personal equation, one printer, practically speaking, registering the same number of tints as another, whereas in the case of colour matching by gazing directly downwards on the meter wide differences in the estimation of what constitutes a tint have been found. A variant of "Johnson's" is the circular meter with disc refills: it is cheaper, but for professional use the former is the better. In some cases cellu-

SUMMARY.

In a leading article reviewing some of the types of actinometer or print-meter we describe how an instrument of the multiple negative type can be very readily made. (P. 46.)

This week's article by "Practicus" on studio work deals with the question of obtaining correct exposures in the studio, and sets forth a system of testing to be adopted in relation to the character of the result which is required. (P. 49.)

The formulae and methods employed by Mr. H. S. Starnes, and recently described before the Royal Photographic Society for a modified process of gum-bichromate are given on page 50.

The properties of a new filter dye, Eastman yellow, are described in a communication from the Eastman Research Laboratory by Drs. C. E. K. Mees and H. T. Clarke. The new dye appears to be an entirely distinct substance from the filter yellow hitherto made by the Germans. (P. 48.)

A short note by Mr. W. E. Debenham contains a caution on the possible fault of register in dark-slides, and describes a readily applied method of testing for any error of register. (P. 51.)

A caution as to the repair of lenses and a further discussion of the assistant question, on which a long letter is sent by Mr. Frank Brown of Leicester, are features of this week's "Correspondence." (P. 55.)

In a report of a council meeting of the Professional Photographers' Association it is mentioned that the trades exhibition annually organised in pre-war days by Mr. Arthur C. Brookes will not be held this year, but that it is Mr. Brookes's intention to hold it in 1920. (P. 52.)

The presidential address before the Royal Photographic Society, delivered by Dr. Atkin Swan on Tuesday evening last, dealt largely with the domestic politics of the Society. (P. 53.)

Photographers in Belfast dependent on electric supply have found themselves unable to continue business as the result of the industrial strike. (P. 53.)

The choice and valuation of studio lenses, cleaning of film from old negatives, use of half-watt lamps, and colouring of prints are subjects on which brief replies are given to correspondents. (P. 56.)

The occurrence of ghost and flare images can often be avoided by the use of an efficient hood on the lens. (P. 45.)

For many purposes a permanent copying installation may be found of commercial value. We describe a method of avoiding any possible distortion from the lens in making copies of plans, etc. (P. 46.)

The shop window is now a much more important consideration in the business of a photographer, and calls for a very careful judgment in the choice of a business position. (P. 46.)

loid is used to protect the tint, but it is an indifferent substitute.

To insure accuracy with thin or medium negatives, the meter should register three or four tints during the printing, accuracy being of more importance when printing platinotype or palladiotype by meter than with the carbon process, which has greater latitude in exposure, or, rather, errors in exposure are more readily corrected in development. But a quick-printing single-tint meter is a decided nuisance when dense negatives are being dealt with, and in such a case a fixed-out lantern plate dyed yellow with bound-on cover-glass can be placed over the meter and will be found very useful to slow down its indications. As a matter of curiosity, it may be mentioned that the extreme variation in the rate of contact printing met with in one trade printing concern ranged from three minutes to twenty hours, the negatives being exposed to the same

Fig.

mercury light, and each negative affording good prints. The perpetrator of the twenty-hour gem had "faithfully promised his customer a dozen prints at the end of the week," as is usual in such cases.

Other forms of print-meters based on tint-matching are illustrated by "Sawyer's" and the "Akuret," the sensitive paper being exposed under translucent tints of different densities. They possess an advantage over the single-tint type, as no movement of the paper is required whilst the negatives are being printed, but their scope is not so wide. The familiar Wynne's meter, dependent upon numbers successively printing out, is a favourite with many, though others experience a difficulty in deciding whether any particular number has, or has not, appeared. Finally, the type first alluded to is the device of Mr. H. J. Burton, on the lines of which the making of an efficient home-made article is to be described.

Not a few have attempted to make print-meters of the graduated miniature negative order, by copying a photograph in the camera, or by exposing by contact a dry-plate behind a positive, in either case successively on different parts of the plate, with an increased time of exposure for each small negative, but this method is very uncertain, and the results are usually far from satisfactory for fairly obvious reasons. It is also obvious, when mentioned, that to attempt to design a meter capable of indicating exposures from thin negatives up to those of extreme density, either means an undesirable multiplication of the tiny guide negatives, or an equally undesirable abruptness in the translation from one to another. For unnaturally dense negatives, one or more pieces of ground-glass placed over the meter will meet the case.

Fig. 1 represents a quarter-plate negative of nine prints stuck on white cardboard, which are reduced by copying in the camera to a little less than 2½ inches high over all, in position shown on the plate. The prints should be of the same subject, preferably a portrait rather large on the plate, and whilst it is an advantage that the set be uniformly lit, even illumination is not essential. Over-exposure is to be avoided as bright, but fast printing negatives with almost clear glass shadows are the most suitable. If the ground prints through it is blocked out.

Assuming the figure to represent the glass side of the plate, and the negatives to read from left to right in the usual way, the graduation in printing rate is effected by covering No. 2 with one layer of celluloid, about the thickness of that used for cut films, No. 3 with two layers, and so on. Fig. 2 shows the first sheet of celluloid applied with extremities extending beyond the miniature negative,

Fig. 2.

but clear of the edges of the glass; on the right about ⅓th inch, on the other three sides more space is available. The next sheet has space 2 cut away, and is stuck down at each end with a touch of celluloid varnish, the procedure being continued *mutatis mutandis* until No. 9 is covered with eight thicknesses.

When the first test of the meter is made everything may appear right, the lower numbers being nicely graded, and on printing further the faint images of the highest numbers apparently the same. But here exists an unsuspected trap, for on printing, say, No. 5, to the "pretty" stage, No. 6 may now be found to be almost indistinguishable in depth, and therefore require further holding back, together with the numbers following it.

Accordingly, the only safe plan is to test each number right through the series at its "pretty" stage against the next less printed one. Some pieces of stripped thin roll-film may be found of service when only a very slight holding back is demanded. The celluloid covering is then edged all round with cardboard slips stuck down with secotine, and a thin cover-glass bound on. If the lower numbers print too quickly for the negatives in use, the cover-glass may be of ground-glass. A three-quarter-view quarter-plate printing-frame holds the finished article; white wood frames are sold sufficiently deep to take it. A packet of 3½ × 2½ ordinary gelatine P.O.P. provides the meter paper, and will keep for years if stored in an airtight tin with some dry calcium chloride. Self-toning papers are not so good for the purpose. When the number indicating the correct exposure is found by trial, naturally only a narrow strip of paper need be utilised afterwards.

In the model constructed, which has worked well, for

identical depths of printing the last number requires about six times the exposures of the first, a range sufficient to satisfy most requirements. This ratio, of course, only holds good for the particular thickness of celluloid employed.

Comparative values might be given each negative if a single-tint meter is at hand, or improvised, by registering the number of tints necessary to bring each negative in turn to the pretty stage.

A NEW YELLOW DYE AND LIGHT-FILTERS MADE FROM IT.

(Communication No. 75 from the Research Laboratory of the Eastman Kodak Company.)

In the early days of orthochromatic photography the dye generally used for the preparation of light filters was picric acid, this having the advantage of simplicity and cheapness and of great efficiency, picric acid absorbing the ultra-violet almost completely, and having a very sharp cut in the spectrum. The disadvantage of picric acid, however, is that it is unstable to light, filters made with it soon turning brown. For this reason the early gelatine filters were made chiefly with tartrazine, which is very stable and gives permanent filters. Tartrazine, however, has the disadvantage that its absorption in the ultra-violet is unsatisfactory, and even moderately deep tartrazine filters transmit appreciable amounts of ultra-violet, this detracting very much from their efficiency. For this reason filter yellow, introduced by Hoechst in 1907, rapidly displaced tartrazine as the best dye for filter-making, and has held that position ever since.

Filter yellow is extremely stable, absorbs the ultra-violet strongly with the exception of a transmission band at $300\mu\mu$, which, since it is absorbed by glass, is of little importance, and has a satisfactorily sharp cut for the preparation of orthochromatic filters. A disadvantage of filter yellow which has always been recognised, however, is the fact that its absorption curve was less sharp than that of picric acid, and for many purposes, especially the preparation of very light filters, a dye possessing the stability and ultra-violet absorption of filter K, but of greater sharpness of cut, would be desirable.

When the need for light-filters of high efficiency for aerial photography arose the need for such a dye became pressing, and we undertook a search for such a material. After a great number of trials it was found that suitable absorption and stability were possessed by the phenyl-glucosazones.

When certain sugars, such as glucose, are warmed with a solution of phenyl-hydrazine in dilute acetic acid, yellow precipitates are produced possessing definite crystalline structures, by which the sugars may be characterised. These yellow substances are known as osazones, those formed with phenyl-hydrazine being termed phenylosazones. On measurement of the absorption spectrum of glucose-phenylosazone it was found that the absorption curve was very sharp and extended far into the ultra-violet, and since the material is well known to be stable, it appeared that a dye prepared from it would possess the properties required for the preparation of light yellow filters.

Glucose-phenylosazone is insoluble in water, so that to obtain a dye it is necessary to have a salt-forming group present in the molecule, and to produce a dye suitable for use with gelatine it was desirable that this group should be an acid one. To obtain such a derivative of glucose-phenylosazone which will form salts with metals it is merely necessary to substitute for phenyl-hydrazine a derivative containing an acid group and condense glucose with it in the same manner. Several such derivatives were tried, and the most satisfactory result was obtained with glucose-phenyl-osazone-para-carboxylic acid. This was prepared in the following way:—

Para-nitrotoluene was oxidised to give para-nitrobenzoic acid. This was then reduced to para-aminobenzoic acid, which was diazotised, and gave para-hydrazino-benzoic acid or phenyl-hydrazine-para-carboxylic acid. The glucosazone of this acid

is a yellow crystalline compound insoluble in water and almost insoluble in alcohol. It forms a sodium salt which is extremely soluble in water, but which can be precipitated from concentrated solutions by the addition of alcohol, and this sodium salt of glucose-phenyl-osazone-para-carboxylic acid has been adopted by us for the preparation of light-filters under the name of "Eastman Yellow."

Fig. 1.

In Fig. 1 are shown the absorption spectra of tartrazine, filter yellow, and Eastman yellow, from which it will be seen that the Eastman yellow has a sharper cut than filter yellow, and almost as strong an absorption in the ultra-violet.

Light-filters prepared from it retain these characteristics, and these light-filters have been prepared and specified under the names of EK 1 and EK 2 light-filters. A special filter for aerial photography has been adopted by the American forces under the name of Aero No. 1.

Fig. 2.

Fig. 2 shows the absorption curves of these light-filters.

As regards stability, it was found on test that the new dye was not quite so stable to light as filter yellow, but was superior to all other yellow dyes tried, and its stability is amply sufficient for the preparation of light-filters, since it requires weeks of exposure to direct sunlight to produce a change even in the lighter-coloured filters.

C. E. K. MEES.

H. T. CLARKE.

PRACTICUS IN THE STUDIO.

STUDIO EXPOSURES.

CORRECT exposure is one of the most important of the factors in making perfect photographs, yet the majority of portraitists approach it in the most casual manner, and apparently trust to a sort of sixth sense to tell them how long to keep the shutter open, or as one said to me, "It is like taking a dive into water; when I press the bulb, I do not know when I am coming to the surface." With long practice it is possible to work successfully in this sub-conscious way, but most people will find it desirable to have some definite idea of the number of seconds necessary to give the exact quality of negative which is aimed at. I want you to take particular notice of those last words. There can be no fixed standard of exposure or density in portrait work, or we should all arrive at one monotonous style, without that touch of individualism which now distinguishes our best photographers from one another. Twenty or thirty years ago there was an established ideal of a clear, sparkling negative ranging from clear glass to opacity, and a high-class operator who did not conform to it had little chance of employment. Many negatives which would be appreciated to-day were then thrown aside as failures, because they were too soft or too hard to print in the limited range of media then available, but now we are more free to choose our methods, and can produce negatives to satisfy our own artistic instincts. Therefore it is necessary if we are to be consistently good in our work we must not trust to "flukes" for our successes, but to study the conditions under which our particular class of negatives can be obtained.

On asking one of our best known outdoor photographers how he secured such uniformly perfect negatives, I was told that they were obtained by "exposing to suit the developer." This was in the pre-Watkins days, when no attempt had been made to systematise development and most people believed that the clever worker owed his success to modifying the developer according to the appearance of the image, often beginning with plain pyro solution, and working up the negative by adding alkali and bromide drop by drop. This idea is now exploded, proving that my friend was a true prophet when he asserted that the prime factor in producing the negative was correct exposure. Messrs. Hurter and Driffield, to whom photographers owe so much, have taught us that the amount of silver affected by light when a plate is exposed is in definite proportion to the length of exposure given, but this assumes that all the silver so affected is reduced by the developer, or, in other words, the plate is "developed right out," which is rarely the case in studio work, most portraitists finding that such a procedure produces too much contrast. This fact has been recognised by both plate and developer makers who prescribe different times of development for portrait, landscape and copy negatives, the former always being much shorter than the latter two.

To establish a correct method of exposure we must make a few experiments, working with a standard developer, and a fixed time of development, which may be obtained by the factorial system, the only variation being made in the exposure. It is convenient and economical, besides assuring uniformity of rapidity in the emulsion, to make several exposures on one plate, and this can easily be done in most studio cameras by fixing a small mask in the camera back and marking the slide so as to show when the plate is in position. The easiest size is to work three upon a half-plate, cutting a mask with opening two inches by four and fixing this in the existing carte or cabinet mask. If the slide has notches for single exposures, and also for repeating two C.D.V. on half-plate, the centre notch may be used, but new marks a little farther from the

centre must be made for the two end exposures. For my own use I have made a repeating back which allows of four exposures, each three inches by two clear, from the rebate upon a half-plate, and this I find handy for many other purposes.

The exposures, which must, of course, be upon the same subject, may be varied in any proportion which the operator desires. Usually double at each step will be found as good as any for portrait work, as our negative will then show us the effect of one, two, four, and eight seconds' exposure. The result will be rather surprising to those who try it for the first time; for, supposing that the one-second exposure gives a thin but printable negative, it will be found that the eight-seconds section, although thick and slow to print, will also yield a passable result. That, however, is not my point, which is that the operator should now select the exposure which gives him the quality of image he wants, or if none quite pleases him should give an exposure between the two which he judges to be nearest correct. So far so good. Now all depends upon correctly estimating the value of the light, and this can better be done with an exposure meter than by the exercise of personal judgment. If we use an ordinary Bee meter and note the time taken to match the tint at the time of making our exposures we shall be able to establish a ratio between meter time and exposure for any light or lighting. For example, if we find that our selected exposure is four seconds, and that it took eight minutes to get the tint, we have the proportion of half a second for each meter minute. Naturally I do not propose that anyone should make meter tests while a sitter waits, but an occasional test between whites can easily be managed. The plate speed and lens aperture must be unchanged, or due allowance must be made, or this system will be worse than useless.

It is often found that when strong effects of light and shade are being tried for that the negatives turn out hard and chalky and do not at all represent the model as seen by the artist. There are two causes of this, both closely connected, under-exposure and over-development, the latter being due to an attempt to force out shadow detail. Now, if development had been done by time without regard to the appearance of the image, we should have retained the detail in the high lights, but the shadow detail would still have been wanting. Longer exposure would remedy this without giving flatness, unless quite an unreasonable time were given. This class of subject affords an excellent field for the progressive series of exposures already recommended; or if it be thought that the effect cannot be judged from so small a plate two full-sized exposures may be made, one receiving three times as long as the other, both being developed for the same time in the same dish.

It is important when making experiments in exposure to keep not only to one make of plate, but to the same grade. Emulsions vary in character, and two grades which are, perhaps, marked 200 and 240 II and D, cannot be relied upon to give the same quality of image, even if the difference in speed be accurately allowed for; much more is this the case if two makes of plate be mixed up. For the same reason one developer should be adhered to, and for printing quality and adaptability to various subjects and lightings there is nothing to beat the old-established pyro-soda. Remember that a negative is only a means to an end, and that "pretty" negatives do not always give the best of prints. Although not strictly within my subject, I feel that at the present time of year it is not amiss to mention that pyro is less affected in its action by variations of temperature than most other developing agents. I have only

recently found the slow action of another developer mistaken for under exposure, with the result that the exposures were increased and flatness resulted.

A point which must not be missed is the effect of the distance between lens and sitter upon exposure. This is always allowed for in copying, but is often overlooked in portraiture. Most operators know that a large head requires more exposure than a full length, other things being equal, but perhaps could not tell you why. There are two reasons, one being the increase in the focal length of the lens as the sitter approaches the camera, and the other the flattening of the lighting by the greater amount of atmosphere which intervenes as the sitter is placed further from the camera. Let us consider the former case, assuming that a head measures 9 inches in height and we are making a 3 in. image of it; this adds one-third to the camera extension, supposing we are using an 18 in. lens working at $F/6$ for infinity; one-third added to the focal length gives us 24 ins.—in other words, we are working at $F/8$, which requires practically double the exposure. When taking a full-length cabinet the reduction would be $1/12$ th.

which would only add an inch and a half to the original focal length, and this we could safely ignore so far as exposure is concerned. In the second case the increase in exposure is only apparent, not real. If there is a certain amount of fog over the shadows it covers the bare glass, but there is no more detail in the shadows than there would be if the atmosphere were perfectly clear. In London, where the atmosphere is as thick in winter as it is in most places, many photographers use a lens of shorter focal length than they would otherwise, in order to avoid this flattening.

In conclusion, let me impress upon the novice that correct exposure is the key to satisfactory results. Leaving colour effects out of the question, any arrangement of light and shade can be correctly reproduced if the proper exposure be given. We can flatten the scale by over-exposure, we can sharpen it by under-exposure, so that if we hit the happy mean we shall get upon our negative what we saw when looking at the sitter. Surely such a consummation is worth taking pains to attain, instead of following the usual "hit or miss" way.

PRACTICUS.

THE GUM BICHROMATE PROCESS WITH A NEW COLLOID.

[The following is the extended account, as published in the Journal of the Royal Photographic Society, of the experiments made by H. S. Starnes and the subject of the paper read by him some time ago before the Society. Mr. Starnes, it will be seen, employs, instead of gum arabic, gum senegal and prepares this latter gum upon the paper in an acid condition. In this respect the process bears some resemblance to that of Mr. Nelson K. Cherrill published some years ago in which arabic acid of gum arabic was previously separated by treatment of the gum with acid.—EDS., "B.J."]

He considered that the bichromate printing process was an ideal one, for the following reasons:—1st. There is an almost unlimited range of colours; 2nd, if suitable pigments are used there is no doubt about their permanence; 3rd, there are no such things as double tones; and, 4th, there can be the same surface of paper as in an engraving. On the other hand, the gum-bichromate process will not give the same fineness of grain that a silver print does, but except for small portraits the grain will probably be fine enough.

In all types of bichromate printing the principal difficulty is in removing only the soluble parts not acted upon by light. In Sir Joseph Swan's original carbon process the film of gelatine and pigment was transferred to a temporary support and the soluble matter was washed away from the back quite satisfactorily, but it required double transfer and warm water. Then came the Artigue process, which did away with the double transfer, but had to be developed with wet sawdust, and frequently the lighter detail would not stand the friction, and was washed away.

Shortly after the advent of the Artigue process the lecturer worked out a process which Sir Joseph Swan told him was the first real advance in bichromate printing since the original patent. The exposed print was soaked in water for a minute or two and laid face upward on a piece of glass, a piece of dry blotting paper was laid over it, and a soft clothes brush was brushed over the back. The soluble part of the film was taken up by the blotting paper, and the insoluble portions forming the image, especially the lighter tints, were pressed down into closer contact with the paper support. Sir William Abney had suggested to him that possibly that method of development might give a suitable grain for process work. The lecturer had no experience of process work, but was pleased to pass on the suggestion to anyone who could make use of it. Although the blotting paper preserved the light detail, still the lecturer had the same trouble as those who tried to revive Pouncey's method of printing very deeply and removing the soluble portions with a wet brush—there was no dependence on the condition and solubility of the gum arabic.

When the bichromate printer was an artist he could remove what he liked and leave what he pleased, but the ordinary worker lacking that ability was likely to give the process up in despair. He felt, however, that there was something in the process if he could get a more suitable colloid than gum arabic. He had gradually worked

his formula down to the point that to get the best results the paper must be coated so thinly that one minim of the combined mixture of water, gum, pigment, and bichromate must cover four square inches of surface. The brush, the sawdust, and the nozzle of the garden hose were all too brutal in removing the pigment, and blotting paper was too expensive. After experiments, he came to the conclusion that a straight tube about 3 in. in length, with a bore about the same as in a tobacco pipe, and fitted to the domestic water tap, answered well, as the force of the abrasion could be controlled by varying the supply of water. When he wished to concentrate the action of the water upon small areas he used smaller nozzles, which fitted over the first one. There was then pleasure and interest in working on every square inch of the picture.

In searching for a suitable paper he discarded most of those used by the bichromate printers for one reason or another. Cartridge paper and the cheaper drawing papers allowed the coating to sink in unequally. Whatman's paper, in addition to being expensive, allowed the pigment to sink in to some extent, which, although just what the water-colour painter wanted to prevent washing up, was not the property wanted when using the bichromated solution. Some pre-war note-papers were better, and he found a paper used in collotype printing which was at first excellent, but later samples were of inferior quality. He was now using a foreign paper obtained from Spicer Bros., and would send a sample to anyone who sent a stamped directed envelope to him at King Henry's Road, Lewes.

Some of the pigments he had tried contained a proportion of dye, which stained the paper. Messrs. Brooke, Simpson, and Spiller had made him a stock of suitable pigments. He used a carbon black modified with blues, browns, or reds, as required.

He found that refined sodium bichromate worked better than the other bichromates, and got a good sample from J. J. Griffin, Ltd. The stock he has was made in Germany, but he hoped that English firms would now make it.

Nine-tenths of the trouble in bichromate printing arose from the varying characteristics and conditions of the colloids used. The conditions in which gum arabic is collected and stored make it hopeless for the purpose. He found that he might get passable results with it from one negative, yet could do nothing at all when working

from another, even though the paper in use was cut from the same coated sheet. The problem had bothered him for years.

He had to make a rather startling statement, which was that under certain conditions the action of light makes a bichromated colloid soluble instead of insoluble. This would explain why the readings of the actinometer were not always reliable, and why one type of negative would give better results than another. The action seemed to be as follows:—When the bichromate is added to the colloid it renders the latter more or less insoluble at once. On exposure to light it slowly becomes quite soluble, and after it has reached that stage it begins to get insoluble as under normal conditions. Different samples of gum work differently with regard to the length of time for those two actions to take place. Freshly-made solutions are more prone to act so than solutions that have been kept for some time.

At first he thought that different samples differed as slow and rapid plates do; then he found that there must be two actions going on simultaneously, because the parts of the print under the densest parts of the negative were darker than under the half-tones, while under the lightest (or clear glass) parts of the negative the prints seemed to print normally, but not with the density that the amount of pigment ought to have given; so evidently some of the gum was not holding the pigment on to the paper. One day he got a print that had a black sky. The trees in the distance looked as though they were covered with snow, and the shadows, which ought to have been the darkest parts of the print, were simply half-tones. That print gave him a clue to the mystery. He showed a print which at the first stage of exposure was a negative from a negative; another showed the two actions going on simultaneously during the same exposure to light, and another which had first gradually been rendered soluble until, by the time it was soluble under the densest part of the negative, the other parts had again become insoluble in their proper sequence, and it was becoming a practically normal print. He was inclined to think that the first stage was purely a physical one, that the bichromate had bound up the colloid too tightly, and that the first thing the light had to do was to unfasten the straps, if he might use that phrase.

About thirty years ago he had written an article for THE BRITISH JOURNAL OF PHOTOGRAPHY, in which he gave a somewhat similar explanation of the action of light on a dry plate.

He had searched through many books on bichromate printing to see if a double light action of this kind had been observed, but no one seemed to have noted the phenomenon. The matter was one of considerable importance, as it accounted for a very common fault in prints. It was often found that bichromate prints break down in the rendering of the lightest tints, because under the densest part of the negative the film, instead of being made insoluble for the lightest tints of the print, would be undergoing just the reverse action, and would be made even more soluble, and would wash away more easily, so that it appeared as though the print had been under-exposed. The lecturer had made many experiments in the hope of finding some method of keeping the film of bichromated pigment soluble, so that the light action should be restricted to its legitimate function of insolubilising it according to the gradation of the negative. It was not until he had worked out the following formula that he began to see daylight:—

A.—Sodium bichromate	1 oz.
Water	2 oz.
B.—Alum, saturated solution	4 oz.
Hydrochloric acid	2 drams

Take one part of A to three parts of B. If with a certain sample of gum this makes the film too soluble, then reduce the amount of B.

Having found gum arabic to be unsuitable, he had tried a number of other celloids, and finally hit upon gum senegal. As an adhesive it was probably not satisfactory, but for printing purposes it works much better than gum arabic, being softer, less brittle, and more under control. It contains 81 per cent. of arabin, as against 70 per cent. in gum arabic.

To make the gum solution a quantity of it is suspended in a bag of wire cage in 1 pint of water, and as it dissolves more is added until one fluid ounce weighs 9 drachms. To measure the pigment a salt-spoon is used which will hold just 20 minims of water, and four spoonfuls of the pigment (strike measure) are taken; the pre-

cise quantity may vary according to the covering power of the colour, and is ground up with 1 drachm of methylated spirit. This is added to 1½ drachms of water, mixed thoroughly, and placed in a test-tube to settle for a few minutes. One and a-half drachms of the gum solution is taken, and to it is added about three-fourths of the pigment solution, care being taken not to shake up the coarse sediment at the bottom of the test-tube, and the whole is mixed well together. The pigment that had settled at the bottom of the test-tube should be re-ground and added to the mixture. To that is added 1 drachm of the sensitising solution, consisting of 15 minims of solution A and 45 minims of solution B. In winter, solution A may be increased to 20 minims. The quantities given will coat about twelve pieces of paper 10 in. x 8 in.

To coat the paper it should be fastened by one corner to a sheet of glass or zinc, supported if necessary on a wooden board, which in turn rests upon a penny laid on the table, so that the device may be revolved easily in any direction. A spoonful (20 minims) of the mixture is poured along the length of the paper from left to right at about ¼ in. from the edge. The colour should be spread evenly over the paper with a 2-in. varnish brush with light strokes, turning the turntable as required, but always keeping the brush flatwise on the paper. If the brush is turned edgewise streaks will appear. With a little practice it will be found quite easy to coat 4 square inches of paper with 1 minim of the mixture.

The coated paper should be placed about 2 ft. from a fire or gas stove, and by the time the second piece of paper is coated the first will be dry. After use the brush should be cleansed with water and a nail-brush and dried thoroughly before it is again used.

The exposure is about one eighth of that required by P.O.P., and is gauged by an actinometer.

For development the print is soaked in water for about a minute and then flooded with solution B (acid alum) 1 drachm, water 2 oz. If the exposure has been correct the colour in the high lights will be seen to float away in a few seconds. The print is then put on a glass easel in the sink and development completed with the aid of the rubber tube and nozzle device previously described. More control over the print is obtained by giving a longer exposure and by using the acid alum solution in a stronger condition.

DARK-SLIDES OUT OF REGISTER.

In three out of four studios that I have visited in the course of the last year or so, I found the dark slides of the camera in general use out of register with the focussing screen. The present use of rapid plates enables the photographer to use diaphragms to an extent that disguises considerably the want of fine definition, resulting from the plate not being truly in focus. In the days of wet collodion, when, in order to secure a portrait free from the unsharpness, due to movement of the sitter, it was the custom to use the lens at full aperture or nearly so, photographers had to be, and were, careful to see that their dark slides were truly in register with the focussing screen.

Although the want of sharpness in the negative, due to the slides not being in true register is less conspicuous when using the smaller apertures to which the use of rapid plates has accustomed us, it is still very desirable that the coincidence of position of the plate and the focussing screen should be as complete as possible, if only for the power obtained to get properly exposed results with the shortest exposures, particularly in the case of portraits of children. A photographer, the proprietor of a high-class establishment, doing a large business, writes me that since the correction of his slides his operator generally takes portraits of children with the open lens with excellent results, and with fewer failures and consequent economy of time and plates.

The plan which I employ to ascertain the truth, or want of it, of the registry of the slides, is to take a strip of wood about ¾ or ½ an inch in thickness, rather longer than the width of the slide, and to drive a screw through it. The strip is laid across the front of the frame of the focussing screen, and the screw advanced until the point just touches the screen itself. A plate is now put in the dark-slide, the back is buttoned down, and the shutter is drawn. The strip is then laid across the front of the slide, and if it is in true register, the screw point will just touch the plate. It is desirable to repeat this trial with the plate placed both vertically and horizontally, and with each carrier that may be in use with the slide. A waste negative is better than a plain glass for the purpose, as a

lamin scratch on the film will indicate very closely coincidence of the two surfaces.

The reason for having the wood a little longer than the width of the slide is (as I have found in one or two cases) that the top or bottom or one of the sides may be higher or lower than the opposite side, and the extra length of the wood allows the screw to be tried on different parts of the plate. The screw is inserted at the place where it will come over the middle of the screen when one of the ends of the wood is just at the outer edge of the frame. This arrangement allows full use to be made of the extra length of wood for the testing the truth of adjustment away from the centre of the screen. The extent of deviation from coincidence is ascertained by placing slips of card of different thicknesses between the point of the screw and the focussing screen, or the plate as the case may be, until a piece is found of a thickness that just fills the space.

If it is the focussing screen that is found to be nearer to the front than the plate, a cardboard matt is cut of the same size outside as the ground glass; about a quarter of an inch wide all round except at the corners, where it is rounded inside for strength. A photographer generally has a stock of old mounts of various thicknesses, but if there is not one of just the thickness required, one or more thicknesses of cartridge paper may be pasted on to a thinner card, and when dry used for the purpose. The card matt is dropped into the frame, and the glass replaced and the slip beading pinned in again.

If it is the plate that is too near the front, slips of card are glued on all round to the rabbet of the dark-slide. It may be that some of the carriers may require adjustment independent of what has been done to the dark-slides. In this case they may be tried by gluing slips of card along the edges of the front, or, if the error is in the other direction, by reducing the thickness of the wood in the same place.

Of course, a neater job may be made by sending the slide and frame of the focussing screen to a camera maker or to an intelligent cabinet maker, if (which is not often the case) the camera can be put out of use for the time, but the home cure method described has answered perfectly well.

W. E. DEBENHAM.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, FEBRUARY 1.

Rodley and District Photographic Society. Annual Exhibition.

MONDAY, FEBRUARY 3.

Bradford Photographic Society. Yorkshire Photographic Union Slides. Also Members' Slides.
City of London and Cripplegate Photographic Society. Ladies' Evening.
"From Alp to Apennine." J. D. Johnston.
Dewsbury Photographic Society. Y.P.U. Portfolio.
South London Photographic Society. "Experiences of a War Photographer."
H. Creighton Beckett.

TUESDAY, FEBRUARY 4.

Royal Photographic Society. "English Prints from Saxon Times to the Sixteenth Century." R. Gardner.
North Wilt's Field and Camera Club. "The Unofficial Side of Aviation." Air Mechanic L. A. Peckham, R.A.F. (Service exigencies permitting).
Hackney Photographic Society. "Portraiture—Its Aims and their Achievement." A. Akerman.
Chelsea Photographic Society. A.P. 1917 Prize Slides.

WEDNESDAY, FEBRUARY 5.

Croydon Camera Club. "Picture Making." R. H. Lawton.
Edinburgh Photographic Society. "Cinematography." Lieut. Haggard.
Tunbridge Wells Amateur Photographic Association. "A Drive into Belgium." W. L. F. Wastell.

THURSDAY, FEBRUARY 6.

Liverpool Amateur Photographic Association. "Three Men in a Car." J. Shaw.
Brighouse Photographic Society. Annual Meeting.
Huddersfield Naturalist and Photographic Society. Lantern Lecture, "Life and Scenery in the Alps." P. Lund.
Hammersmith (Hampshire House) Photographic Society. Joint Exhibition of Rodley and District Photographic Society. Members' Night.
Wimbledon Camera Club. Velox and Transferotype Demonstration. Mr. Slater.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the Council was held on Friday, January 17. Present:—Messrs. G. Hanna, A. Basil, Gordon Chase, A. Corbett, C. F. Dickinson, A. Ellis, S. H. Fry, W. E. Gray, R. Haines, A. Mackie,

Lang Sims, R. N. Speaight, H. A. St. George, F. G. Wakefield, Marcus Adams, Frank Brown, W. B. Chaplin, T. Chidley, Montague Cooper, P. Lankester, H. C. Spink, and A. Swan Watson.

The Hon. Secretary reported that the Government scheme of demobilisation of owners of one-man businesses afforded an opportunity for the Association to do more to secure release from service than could be done by the man himself or his wife. The scheme was in itself simple and complete, and any failure could only be due to errors of administration.

The Hon. Secretary read a draft of the Report of the Council to be presented to the annual general meeting, which was passed.

The Hon. Treasurer presented his balance-sheet, and in commenting on the figures showed that although the number of subscriptions collected exceeded that in any previous year, and there was a small balance of receipts over expenditure, the increasing expenses of conducting the Association owing to high prices in every direction, including the cost of producing the P.P.A. Circular, would necessitate raising the amount of the subscription.

Report of the Committee appointed at the last meeting of the Council upon Mr. Adams' scheme was read, in which the raising of the amount of the subscription was advised.

After discussion it was decided to propose at the annual general meeting an alteration of the rules to raise the annual subscription from 5s. to 10s. per annum.

The Hon. Secretary reported that he had had a conference with Mr. A. C. Brookes, and learnt that it would not be possible to hold an exhibition at the Royal Horticultural Hall this year, as the Government were retaining possession of the building, and there was no other building in London available, but he intended to hold the exhibition in 1920.

At the conclusion of the business a special meeting of the Council was held in accordance with rule 12 to nominate a President and twenty-four members of Council to serve during the ensuing year.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, January 28, the President, Dr. C. Atkins Swan, in the chair.

The President delivered his annual address, in which he first of all briefly reviewed the state of photography during the war. In lenses and cameras, as used in aerial photography, he was happy to say that the Germans had been beaten in manufacture. He had had opportunities in France of seeing the inferiority of their instruments at different stages of the war, and he had obtained official confirmation before making the statement. In chemicals he said it was only necessary to refer to the name "Johnson" in order to point to the supply of chemicals previously supplied by the Germans. He referred also to the Paget process of colour photography of which good use had been made in the war.

Turning to the domestic affairs of the Society, the President uttered a strong plea for a full co-operation in its progress by the whole body of its members. He instanced many directions in which their efforts could be extended and said that it was his desire to see the Society's house the headquarters of all kindred photographic societies and the centre to which anyone interested in photographic matters would naturally gravitate. In regard to the presence of persons of enemy nationality previously on the books of the Society, Dr. Swan made it very clear that were they to be re-instated he would resign from his presidency. Loud applause followed his declaration that, after the brutalities of the Germans, they could never be received again.

On the proposition of Mr. John H. Gear, seconded by Dr. Rodman, the thanks of the meeting were accorded to the President for his address.

CROYDON CAMERA CLUB.

THE club got nicely hoist with its own petard last week when Mr. R. H. Lawton, F.R.P.S., gave a lecture on "Picture Making." It was illustrated by many of his works, which, it may be said, really deserved the appreciation he expressed about them, and no higher praise can be given. How far he was pulling the leg of everyone present remains a matter of doubt; that he succeeded in highly amusing all, making things go with a swing, and imparting much useful information is a matter of fact. Hailing from Ilford,

this Society, as represented by Mr. Lawton, outplayed Croydon at its own game.

He began by saying that he arrived as the Apostle of Faking, which was the highest form of technique regardless of what scoffers might say. He knew he was right, and this being so, contradiction was obviously futile. With exposure meters it was as simple as simple could be to turn out technically perfect negatives. Although a truly great man in many directions, he took no credit for invariably producing such.

He then passed round a straight print from a mechanically made negative and defied any to find a single blemish, adding that all of the many exquisite works of art to be shown were numbered, so that none could be appropriated without the fact being discovered. "It is a large assumption that any will desire to do so," here remarked a member dealing the first counter-blow.

The lecturer next dealt with the control methods employed by him, which are on similar lines to those recently demonstrated by others, viz. :—a liberal application of blacklead, or sepia powder to bromide prints, in his case applied with a Bromoil brush. These diversions have been fully recorded, and need not now be discussed. Many negatives were made by copying in the camera worked-up bromide prints, and he maintained no loss of quality need ever occur in the process. When enlarging he had found two or three separated layers of chiffon on the lens introduced a soul into the picture.

In-reference to retouching, he scornfully derided those who adopt a standard stipple for all subjects. He employed a dozen different strokes and showed some on the blackboard, the correct "silver birch trunk" touch being much admired. With portraits, freckles demanded a series of radiating lines meeting each other about the centre, which thus received the most lead. Retouchers who have been accustomed to work in other ways should now realize how fatuous they have been. He strongly recommended the medium of the Autotype Co., and advocated that the pencil should be so finely pointed as to break off directly it was applied. This is a point often overlooked. Unfortunately, the cogent reason he gave is forgotten. Before applying the medium the film should be bone dry; if not, a coarse grain may result. With the fine retouching obtained by him, and possibly by others less gifted, any degree of enlargement should not render it obtrusive. Enlargements made by him up to 24 by 18 (inches or yards not specified) showed not a trace of handwork applied to the original.

Composition was now tackled, introducing the mystic "S" and "7" business. The former is fairly complete in itself; the latter requires balance. The necessity for a good stock of sky negatives was insisted upon, and he thought nothing of waiting years for a sky to turn up suitable to fit a landscape in hand. As regards photographic critics in general Mr. Lawton delivered the most unflattering opinions. Mr. Tilney was an important exception, having expressed appreciation of his (the lecturer's) pictures on more than one occasion. Once he exhibited a perfect gem at his Ilford Society. It sounded almost incredible, but the judge never even awarded an "honourable mention." Giving his reasons for the awards, a conflict occurred between him and the exhibitor. "I have been studying photography for thirty years, and ought to know what I am talking about," said the judge, not in the best of temper. "I have been studying Nature for the same time, and do know what I am talking about," snapped the exhibitor. The print was then sent to many exhibitions and secured the first award in all, refused by the R.P.S., tendered again the next year, and accepted.

In the discussion Mr. H. P. C. Harpur said tulle was better than chiffon for diffusion. Being the inventor probably he was right. Mr. J. Keane felt very sad that the lecturer had sniffed at Bromoil. Why this sniffiness? Mr. J. M. Sellors was delighted with the advocacy for blacklead, etc., for powdering in art on bromide prints. On the other hand, the process might be terribly dangerous, resulting in horrible monstrosities. In this contingency it should be understood that Mr. Sellors was referring to the work of others, which is usual. Mr. E. A. Salt denied that the average pictorialist produced technically perfect negatives. Generally the reverse. First-class printers were not so easy to secure as had been made out. The lecturer's remarks on copying must be accepted with qualifications. Given a high-class printing negative full of

gradation and extended range, say, of the usual professional portrait type, then no copy of a print would quite equal the original.

Mr. Lawton, in reply to Mr. Keane, denied sniffing, but he certainly had one objection to Bromoil, and that a big one. His method was slow and sure, allowing unlimited time for judgment to come into play. The Bromoilist had to work so fast that unless he was a trained artist false tonality and other errors were bound to be introduced. Far better for such to abandon the process and take to breeding rabbits instead, a safer and more profitable pursuit. A most hearty vote of thanks was accorded the enterprising lecturer.

THE SHEFFIELD AND DISTRICT PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.—By invitation, this association's January meeting was to have been held in the studio of the President, Mr. G. T. Dickinson. The illness of this gentleman, however, compelled the cancellation of this arrangement. Miss Ethel M. Eadon very kindly invited the association to meet in her studio, Glossop Road; and the invitation was gratefully accepted. A fair number of members spent a very pleasant evening, and, while little business was done, all thoroughly enjoyed the opportunity offered to inspect a very highly-organised and well equipped studio. A hearty vote of thanks was accorded Miss Eadon for her kindness. The S. and D.P.P.A. want more members.

FORTHCOMING EXHIBITIONS.

February 10 to 22. Glasgow and West of Scotland Amateur Photographic Association Inter Club Exhibition. Secretary, Gilbert S. McVean, 125, West Regent Street, Glasgow.

February 20 to 22.—Leicester and Leicestershire Photographic Society. Secretary, H. C. Cross, 80, Harrow Road, Leicester.

February 22 to March 8.—Edinburgh Photographic Society. Entries close February 13. Secretary, George Massie, 10, Hart Street, Edinburgh.

Commercial & Legal Intelligence.

NEW COMPANIES.

PRECISION LENS MOLDING Co., LTD.—This private company was registered on January 15, with a capital of £2,000, in £1 shares. Objects: Pressers, moulders, and shapers of glass and other materials in preparation for the manufacture of lenses for optical instruments, and for other purposes, etc. The subscribers (each with one share) are:—C. H. Watson, 313, High Holborn, W.C., manufacturing optician; F. W. W. Baker, 313, High Holborn, W.C., manufacturing optician. First directors:—C. H. Watson, A. H. Emerson, and W. E. Oakden. Registered office, 3, Chapel Place, White Hart Lane, Tottenham, N.

THE BELFAST STRIKE.—Owing to industrial strikes, Monday morning last found Belfast without gas or electricity. Darkroom work in the local studios was seriously handicapped while photographers entirely dependant on electric studio illumination were unable to commence business.

AUSTRALIAN WAR PHOTOGRAPHS.—A valuable record of Australia's part in the war has been published in pictorial book form. The volume contains 170 photographs, of actual fighting and other war scenes, taken by the Australian official photographer, Captain Wilkins, M.C., who, by the way, was the photographer with the Stefansson Arctic Expedition. The collection covers operations from November, 1917, to the signing of the armistice. The cover bears a typical war sketch by Lieutenant Fred Liest, and the introductory note is written by Mr. W. M. Hughes, Prime Minister of Australia, who says:—"This collection of photographs will be absorbingly interesting to all Australians, for the places portrayed have been made famous by the deeds and sanctified by the blood of their kinsmen." The book is obtainable at the A.I.F. Publications Section, Australia House, Strand, London.

News and Notes.

FRENCH LUXURY TAX AMENDMENT—Private advices from Paris (writes "The Times") show that the French Government has under consideration a new measure for modifying the luxury tax, which has not yielded the results which had been hoped for. It is proposed to exclude certain goods, such as photographic accessories, from the operation of the tax entirely, and to limit the tax on certain articles to those costing 250f. (£10) or more. If the proposals are carried through, a suit of clothes costing 300f., which at present is liable to a tax of 10 per cent. on the full amount, would be taxable to the extent only of 10 per cent. on the excess over 250f., which would mean a total payment of 5f. It is also intended in view of the further general rise in prices to raise the price limits which determine whether articles shall be classed as luxuries or not.

JOURNALISTS' WAR MATINEE.—A great Victory matinée which is being organised by the National Union of Journalists in aid of their War Distress Fund for the dependents of all British sailor, soldier, and airman journalists killed in the war, will take place at the Coliseum on Sunday next (February 2). A splendid and varied programme has been arranged by Mr. Oswald Stoll, the artists including Miss Ellen Terry, Miss Lily Elsie, Miss Teddie Gerrard, Miss Lydia Kyasht, Miss Madge Titheradge, Mr. Mark Hambourg, Mr. Nelson Whelan, Mr. Alfred Lester, Sir John Forbes-Robertson, Mr. Albert Whelan, and the Gresham Singers.

Mr. George Robey, C.B.E., will hold an interesting auction, in addition to giving a special performance. Among other items, he will sell an autographed copy of President Wilson's "Fourteen Points," which the President has sent to aid the funds. Lord Weir has given a German propeller taken from a captured Fokker triplane (the same type as Baron von Richthofen flew), and Sir Henry Trenchard, Commanding the Independent Force, R.A.F., has forwarded a unique photograph of the German town of Offenbourg taken during an air raid. Sir Ian Hamilton has presented for sale a tobacco-box shot off his table in Gallipoli, and General Sir John Monash, the Australian Commander, the sword which he fought with during the same campaign.

The Journalists' Committee hope, by their effort, to secure sufficient funds to enable them to avoid further appeals. Seldom have journalists appealed on behalf of their own people, while always lending a helping hand to other causes, and they now look to the public for support to make this matinée a great financial success. There are still several boxes and stalls to dispose of. Application for these should be made at once to the Coliseum or to the Matinée Committee, 180, Fleet Street, E.C. Donations to the War Distress Fund, which will be heartily welcomed from those who cannot attend the matinée, should be sent to the latter address.

ARE MATERIALS PRICES TO FALL SOON?

To the Editors.

Gentlemen,—It may interest your many readers to know that the days of cheaper sensitive materials are now not very far off, and that we shall shortly have suave and smooth-tongued commercials calling upon us begging and praying us to give them orders.

The "writing on the wall" appears this week in the "Labour Gazette Supplement" issued by the Government. For many months it has been part of my work to deal with certain items in this special "Supplement," and I have watched it grow from practically nothing to a more or less healthy publication consisting of eight very crowded pages. This official list, as some of your readers may know, contains the names of people to whom contracts have been given by the Government, and as a photographer I have been in the habit of turning first to the sub-heading "Photographic Stores" in order to see and make a note of the various photographic firms securing Government contracts, and as a consequence have never

marvelled at the great increase in prices of sensitive materials and apparatus.

Yesterday I had delivered to me the current issue of the monthly "Supplement," and oh, Hamlet, what a falling off was there! The official list of War Office and other contracts given out by the Government has fallen to three and one-quarter pages, and no names of photographic firms or manufacturers appear in the list! The sub-headings go from "Paint" to "Pumps," "Puttees," and other necessities without a word of apology from the Government. Names which have appeared so regularly are missing for the first time since prices of dry plates and papers were put up so high.—
Yours truly,
H. GANN.

BRITISH GELATINE.

To the Editors.

Gentlemen,—In reference to what has recently been said of the war achievements of photographic manufacturers, we feel that we are justified in writing to you on what we consider to be a very important subject.

In addition to ourselves there is only one firm of English emulsion gelatine makers in this country, and previous to the outbreak of war manufacturers of dry plates, papers, and films obtained their principal requirements of emulsion gelatine from the Continent, especially Germany. Since 1914, when the importation of enemy goods was prohibited, the English photographic firms have obtained their supplies from ourselves and our only English competitor. We are sure you will appreciate the fact that if the two firms had not been in existence the photographic firms would have been placed in a very serious position; they would have had large numbers of orders to execute for the R.A.F., the Admiralty, the War Office, the Medical Supply Department, the India Office, and other Government departments, but where the necessary gelatine would have come from would have been a very difficult problem, as the French emulsion gelatine manufacturers had more than they could cope with in keeping the home trade supplied.

You have commented several times in your journal on every branch of the photographic industry but ours, which, unfortunately, you have passed over, through inadvertence, no doubt.

We feel that in justice to ourselves and to our only other competitor that some recognition of our services to the trade in a time of great difficulty would be some sort of compensation for all we have endeavoured to do during the past four and a-half years, in helping the photographic manufacturers to supply the demands made on them, and thus, in an indirect way, assisting to bring the war to a successful termination.

Trusting you will give this matter the publicity it deserves, we are, yours faithfully, for and on behalf of the British Gelatine works, Limited,
L. J. HENRY, Secretary.

London, January 25, 1919.

LENS REPAIRS: A WARNING.

To the Editors.

Gentlemen,—Many who have had cameras put aside "for the duration" or until a return to civvies became possible and Dora dead and buried, are now getting their cameras ready for the good time that we are led to believe is to come. To such workers—who invariably do small camera repairs—a word of warning is, I think, necessary.

Most of us know by experience that lenses often stick very tightly in their mounts, or mounts in their flanges, and refuse to be loosened, lenses mounted in aluminium being, as a rule, the worst-offenders. Dodges galore for unscrewing stuck lenses have been published, all of which methods may answer well enough with lenses in mounts of brass, but any attempt to use undue force with modern aluminium mounts may lead to disaster because of the peculiar nature of the material.

Iris stops also have a nasty habit of becoming fast and immovable if put aside and not used for a time, particularly if the leaves of the iris are made of vulcanite or similar fragile material; in no case is it advisable to attempt to twist unduly any iris diaphragm that has become quite fast or even very stiff. I have also found that few dealers who undertake camera repairs will take in hand a tightly fixed aluminium lens or one with fixed vulcanite stops, they invariably recommending the unfortunate owner of such lens to send it direct to the makers, and even the latter have been known to fail.

Only this week I have a letter from one of our best-known lens makers to whom a fixed lens was sent for removal—a very costly aluminium objective which a dealer refused to handle. The letter states that the lens cannot be returned in two days, as promised, but that the lens will be returned in about a fortnight, they accidentally smashing the lens in their attempt to unscrew it. The moral of this tale is obvious, for if the makers with their correct and special tools cannot do the work of unfastening a stuck lens without injuring it, it is certain that we professional photographers cannot, so perhaps your readers who find themselves with fixed lenses or iris diaphragms of a more or less brittle character will take warning.—Yours faithfully,
GODFREY WILSON.

THE ASSISTANT QUESTION.

To the Editors.

Gentlemen,—I trust that every encouragement and support will be given to Mr. Marcus Adams in his excellent suggestion upon the Assistant question. Let every assistant who values his future welfare immediately communicate with Mr. Adams, so that a complete register can be compiled of all assistants. The record and ability of each assistant can then be registered, giving some idea of their capabilities.

A register should also be made of all studios, so that assistants, when taking up new engagements, will have some idea of the class of work they are going to.

Many an assistant has taken a long journey, at great expense, only to find himself in a business of the "cheap and nasty" type. If he had been able to apply to the proper quarter for particulars this disappointment and expense would have been avoided. The establishment of a governing body will be beneficial to both masters and assistants.

It will also be the first step towards settling many other vital questions which affect photographic assistants. Let all unite; it is the duty of all to try and better the conditions under which we work.

I would urge all assistants to point out to their fellow-workers the importance of taking an interest in this great question. They should send their suggestions and opinions to Mr. Marcus Adams, 29, Blagrove Street, Reading.—Yours faithfully,

ALFRED E. J. THOMAS.

2, Brighton Road, Cheltenham.

To the Editors.

Gentlemen,—The correspondence lately appearing in this "Journal" under the above heading is becoming both interesting and instructive, inasmuch as one sees the heartening sign that assistants are beginning to wake up and take notice, also that their ideas and requirements, individually and collectively, are being circulated generally and openly brought forward for discussion.

The subject of the relationship between employers and assistants is one that some years ago I introduced at a meeting of the P.P.A. during a Congress Session, and at the time my remarks were listened to with, I believe, some considerable sympathy. The prevalent opinion on that occasion, however, was that assistants as a body were somewhat apathetic, or that probably they had little to complain of. One of my points was with respect to specimens of assistants' work, a matter to which I hope to refer again, with the permission of the Editors, at no distant date, making certain propositions which I feel will be practical and beneficial to both employers and employed.

To regulate matters between the two, however, appears to be a somewhat difficult problem, if one seriously notes the variety of complaints brought forward in the recent letters to the Editors by more or less aggrieved assistants, but personally I consider the task far from hopeless if properly grappled with.

That it can be satisfactorily taken in hand is certain, and that the Council of the P.P.A. are anxious and willing to render every assistance in so doing is a fact of which I am absolutely sure.

A sub-committee of the Council has been recently formed, and through my friend Marcus Adams has issued an invitation for opinions and suggestions for the benefit and welfare of assistants from anyone and everyone interested; with what success we shall be notified in due course, I have no doubt. Possibly Mr. Adams

may be somewhat discouraged to begin with, but he and his co-workers on this sub-committee are men of perseverance and optimism, and will not go under without a struggle, once having started upon the course.

There is a saying that "The gods help those who help themselves." Assistants are evidently desirous of doing something for themselves, and if that something is done in the right manner and in the right spirit it will be to their advantage and to the advantage of their employers also.

It therefore seems to be a question of procedure, and my own opinion is that individual effort on the part of assistants, in various ways I may propose later, will be of far greater value than any combination, which has been frequently suggested, without it be a combination of principals and employees, a federation I would look upon as being both practical and ideal. A "Union of Photographic Workers" may sound very well and look important on paper, but to my mind, in the present state of events, its creation is both unnecessary and undignified—undignified because it has been suggested by a correspondent, "W. E. B.," referred to below, that such a combination I might advocate should act if "an employee be dismissed against his desire," and unnecessary because no decent employer would, without grave financial reasons or others equally urgent, wish to dispense with the services of a good capable assistant without an effort to secure for him or her another good berth.

This correspondent also proposes that assistants should pass an examination to qualify themselves for a minimum wage. Such a procedure was inaugurated some years ago, and a scheme of three grades, I believe, worked out, but the response was so very, very limited that the whole thing fell into desuetude, and was finally abandoned.

Photography is a strange profession. It is a good one if only that it tends towards the artistic, and artistry in all forms is elevating.

But what degrees we have in photography—and photographers? For one thing it would be interesting, as I remarked at the Congress meeting above referred to, to know how many men practising photography as a business at the present time were duly apprenticed, and how many were not. It is probably to one of the latter portion of the fraternity that the correspondent "W. E. B." (issue January 10, "I.J.") alludes when he remarks in his letter, "No thanks to the employer to whom he was apprenticed," when complaining of indifferent wages.

There are many photographers as professional men who were like myself, formally apprenticed, and who love photography for its artistic possibilities; there are others who have not, as we might say, been legitimately articleed who see the purely commercial side only, but it is up to the would-be apprentice, or his friends, to use discrimination at the outset and not get bound into such businesses. Here I am hopeful that the P.P.A. will in time be useful to beginners, with respect to its insistence on certain and perhaps rather more stringent qualifications on the part of its members.

So much for the employer. Now what about the assistants? Do they help themselves as a body by attending classes in art or chemistry? How many recognise the utility and helpfulness of one or the other or both? How many of our young retouchers—and old ones—for that matter—know anything of facial anatomy? So many of them can "work up" a negative with a beautifully fine stipple, and at the same time bring every bit of modelling out of the face, eliminating character and thereby nullifying much of the conscientious work of a skilful operator in the studio.

Do some of our printers and dark-room assistants know the meaning of chemical cleanliness, or even ordinary cleanliness, in connection with their work? Some admittedly may have indifferent surroundings, but if that be the misfortune and not the fault of the employer there is an opportunity for a good assistant to make his presence felt and valued more highly.

The crux of the situation, then, is, to my mind, the urgent necessity of helping each other, and I firmly believe that events of the last four or five years, although in some respects deeply deplorable, have shaken things up in photography, and that photographers, both rank and file, are ready for the "gods the gods provide," and to take every advantage thereof.—Yours,

Leicester.

FRANK BROWN.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelopes is enclosed or reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

- I. J. BRUNER.—The silver image is converted into silver chloride plus some chromium compound, which remains attached when the haloid salt is reduced by the redeveloper.
- M. P.—The lens is the ordinary or Petzval type of portrait combination for cabinets. The equivalent focal length is about 11 inches, and the aperture between $f/3$ and $f/4$. The list price was £9 15s.
- P. W.—The nearest publication is the "Photo-Revue," issued at present fortnightly from 118 and 118b, Rue d'Assas, Paris (VIe), price 25 centimes (about 4d., including postage). The latest issue is that of January 15.
- A. J. H.—We cannot say whether the numbers referred to of the Journal are still obtainable, but the Secretary of the Society of Chemical Industry, Central House, 46 and 47, Finsbury Square, London, E.C.2. will give you particulars. To non-members of the Society the price for single current copies is 2s. each.
- A. F.—The gum-water spray on your coloured work is pretty certain to cause some amount of running. Why do you not try it on a small piece of work? The usual method of brightening enlargements in this way is by the use of a fixative varnish, such as you can get from the Aerograph Company, 43, Holborn Viaduct, E.C.1.
- A. C.—We do not think that you can do better than to get a $f/5.6$ anastigmat of about $8\frac{1}{2}$ ins. focal length. This should do all the classes of work you mention. We cannot specify any particular make, as practically all the well-known varieties are of first-rate quality. If you purchase a second-hand lens be sure to get it on trial first.
- M. E.—There is no book on the subject. A very comprehensive article on half-watt lighting appeared in the "B.J." of October 26, 1917; the issue is still obtainable from our publishers, price 4½d. post free. The General Electric Company, 67, Queen Victoria Street, London, E.C., supply the lamps; they will send you their catalogue on application.
- W. M.—Any ordinary large looking-glass placed on the floor to reflect the light upwards will answer the purpose. Pull a couple of lamps down as far as they will come so that the light does not have to travel too far, or the exposures will be very long. You may have a little diffused light in the studio, but the principal light must come from the mirror, and this should be almost direct, i.e., not diffused.
- F. H. S.—The only book on tinting is "Colouring Photographs and Lantern Slides," by R. Penlake, price 1s. 6d., from Messrs. Iliffe, 20, Tudor Street, London, E.C. You will get also some useful hints in the directions for their use issued with the set of dyes by Mr. A. V. Godbold, 98, St. Asaph Road, Brockley, S.E. For terms for postal lessons you should apply to Photographic School, Regent Street Polytechnic, London, W.
- B. H.—The method used by commercial sellers of old negatives in order to clean off the emulsion film is to dip the plates in nearly boiling solution of caustic soda. This removes the emulsion very quickly, but we know of no method sufficiently rapid which would enable you to recover the silver or the gelatine. The latter, we think, would not be of any commercial value, and,

in fact, it is usually considered that the emulsion remaining in gelatine negatives is not worth recovering.

W. W.—The easiest rule we can give you is as follows:—Imagine a distance in front of the lens equal to one focal length, and a similar distance behind it also one focal length. Then, if in photographing an object at any distance the image is $1/n$ the linear dimension of the object, there will be n focal lengths in the space between the object within the imaginary focal length in front of the lens and a distance of $1/n$ focal length between the image and the imaginary focal length behind the lens. This relation of n and $1/n$ for n times reduction should enable you to carry out any necessary calculations.

R. M.—The prints appear to be made on collodio-chloride paper and toned with platinum, the formula for which is given with the paper. Seltona or Paget self-toning paper will give this result. Nearly this tone may be obtained by using a salt solution and a very strong hypo solution on either of these two papers. We know of no toning bath that will give quite this result on bromide paper, although Kosmos Vitegas very slightly toned with liver of sulphur comes very near it. The prints should be taken out of the toning bath as soon as any change is apparent, as the colour gets warmer in the washing water. Illingworth paper also gives a purplish tone with liver of sulphur.

C. A. W.—(a) We should prefer to stick absolutely to the maker's formula. We think it is unwise in view of the cost of Autochrome plates to endeavour to economise to the extent of a few pence in making up the developer. (b) It is near enough to use .880 ammonia instead of .920. (c) Dianol is similar to amidol, and should be used in preference to a paramidophenol developer such as azol, though no doubt the latter would serve for redevelopment. (d) We cannot say from experience. The best plan is to keep within 60 and 65 degs. F. (e) No objection to using metabisulphite instead of bisulphite in the fixing bath. Use formula given in the "Almanac." (f) Of no material effect. (g) It can be used. (h) The acid silver method is preferable on account of its continuous action, and of its facility for stopping intensification precisely at the stage required. (i) A mistake to depart from the regular formulæ. We should be very loth to risk developing Autochromes together by tank.

The British Journal of Photography.

IMPORTANT NOTICE.—Advertisers are requested to notice that the prices printed below represent an

Increased Scale of Charges,

which is now in operation in respect to all line announcements.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind this revised tariff. They will thus save themselves delay in the publication of their announcements.

Net Prepaid Line Advertisements.

Increased Tariff of Charges.

12 words or less	1/-
Extra words	1d. per word.

(No reduction for a series.)

Special Note. Adv'ts under a Box Number.

"Box No." and office address charged as 6 words.
 For forwarding replies add 6d. per insertion for each adv't.
 If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.
 Orders to repeat an adv't must be accompanied by the advertisement as previously printed.

Advertisements are not accepted over the telephone.
 The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.

Displayed Adv'ts should reach the Publishers Monday morning.
 The insertion of an Advertisement in any definite issue cannot be guaranteed.

SUMMARY.

In this week's article by "Practicos" the various methods of employing the electric light in the portrait studio are succinctly dealt with, simple instructions for installing arc and half-watt lamps being given. (P. 59.)

The price of materials and the assistants question are the principal subjects dealt with in "Correspondence" (P. 63.)

An interesting note on the troubles of Belfast photographers during the riots will be found in page 62.

The Lancashire and District Master Photographers' Association will have a dinner on February 25, and an exhibition of members' work on May 27. It is hoped that all photographers in the district will do their best to make these functions successful. (P. 62.)

Much money is yearly lost by wasteful methods of storing and using chemicals. Some hints on this subject which should be welcome at the present time are given in an article on page 58.

The possibility of making successful "living portraits" of private sitters with a suggestion for their display forms the subject of a paragraph on page 58.

A point of interest to assistants who expect replies to letters applying for positions is discussed on page 57.

Spots on prints, flashlight work, packing framed pictures, and combined developing and fixing are among the subjects dealt with in "Answers to Correspondents." (P. 64.)

A formula for re-developing bromide prints to a purple tone resembling gold-toned P.O.P. is given in a letter on page 62.

Failures in making the iodine-cyanide reducer, with instructions for obviating the principal difficulties, are dealt with on page 57.

The necessity for thoroughly washing bromide prints, an often neglected operation, is referred to on page 58.

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

The full specification of what promises to be an important step forward in the three-colour subtractive process, in which only two plates are needed for producing the three-colour elements, forms the major part of the Supplement this month. The patent has been granted to Mr. E. E. Ives and the Hove-Ives Corporation. (P. 5.)

Details of an imbibition process by means of which it is claimed that reproductions upon paper may be made by printing direct from a screen-plate positive are given on page 8.

Colour processes, including those of Drac and Herbert E. Ives, are described in "Decennia Practica" on page 7.

EX CATHEDRA.

Stamps and Box Nos. What is alleged by a correspondent to be a grievance amongst assistants who apply for situations advertised over a box number is the non-reply to such applications when a stamped and addressed envelope is enclosed for the purpose. It has been suggested more than once that the publishers of the "B.J." should devise some plan by which the grievance should be removed. Out of curiosity we should like to know of a plan which would achieve this end, for we can conceive of none but that which applicants have in their own hands, viz., to refrain from sending stamps for this purpose. In this matter it is necessary for an applicant to put himself in the position of an advertiser who receives a score or more replies to an announcement. Naturally the applications from those who seem suitable are replied to, but the general commercial practice is to leave the others unanswered. That being so, the enclosure of a stamped and addressed envelope imposes on the advertiser an obligation which he has not invited, and which, therefore, he may disregard. No doubt there are some employers who will reply to every application from motives of old-fashioned courtesy or from a wish to obtain a reputation for consideration, but the majority will never think of it. And the assistant may be asked to think that the enclosure of payment for reply will not in any degree improve the chances of his engagement. It is inconceivable that any business man will be influenced in his choice of an assistant by the fact that he is saved the cost of three-halfpence in communicating with him. On the other hand, he may very easily interpret the fact as evidence of nervousness or want of confidence on the part of the applicant.

Iodine-Cyanide.

For some reason or other the compounding of this reducer of prints and negatives is the cause of more queries to us than is any similar preparation. The failures of which our correspondents complain may be roughly divided into two classes:—(1) Making the iodine solution, and (2) ensuring activity of the mixture. Failure under No. 1 can be infallibly avoided by working in a certain way; that of No. 2 arises from the varying strengths of commercial cyanide, and calls for adjustment by trial of the proportions of the two solutions. As regards the iodine, the secret of causing it to dissolve completely and quickly in the iodide is to add only just enough water to dissolve the crystals of the latter—scarcely more than required to cover them, for they are very soluble—and then to stir in the iodine flakes. These will dissolve almost instantaneously, and will remain in solution on diluting with water to the required volume. But if this latter is used for dissolving the iodide, the iodine is soluble in it only

by the exercise of an enormous amount of shaking or stirring, and usually cannot all be got to dissolve. In regard to the second point, inactivity in reducing power of the mixture of iodine and cyanide solutions is very often due to insufficient cyanide. The latter may be largely contaminated with cyanate which is inert in forming the reducer. Therefore, if the solution does not act as it should, further cyanide solution should be added; and if that fails, the solid cyanide is probably of too impure a quality, and a brand of guaranteed 80 or 90 per cent. should be bought. The reducer, of course, is not active unless containing a proper amount of iodine, which is used up in the treatment of prints, but, given that due proportion, want of energy in bleaching the silver deposit is occasioned by insufficient real cyanide.

* * *

"Close Up" Pictures. A little point which we have noted in several excellent cinematograph films is the very flat lighting in the large pictures of the leading actors and actresses. As most of our readers are aware, these are interpolated between the scenes in order to show more clearly the emotions which the character is supposed to be displaying. The effect is somewhat marred when the face is a ghastly white, and the make up of the eyes and lips the only visible things. That this is unavoidable cannot be urged, for we have seen some such productions which would vie with finished portrait work, and it would seem that the defect is only due to a neglect to arrange for the special lighting which is necessary for a single face. On looking at good examples of this work we have wished that it were possible to make portraits of private sitters in the same way. There would be, we are sure, a good market for them if they could be produced at a reasonable rate, and a satisfactory method of showing them devised. The ordinary projection apparatus is bulky and inconvenient, and cannot be readily used in daylight. Probably many of our readers remember the original Edison apparatus in which the films were inspected by means of an apparatus somewhat resembling a magazine stereoscope, the illumination being by means of an ordinary incandescent electric bulb. In this apparatus the film was in the form of an endless band, so that the episode could be repeated as often as possible without re-winding. Some time ago we saw a cylindrical film on which the pictures were arranged in a spiral somewhat like a phonograph cylinder. If this idea could be carried out in a satisfactory way it should become popular. There have been attempts to make home cinematographs working with glass plates, but these are too fragile and cumbersome to appeal to the non-technical public.

* * *

Print Washing. As a rule it is some little time before the presence of hypo in an imperfectly washed print becomes manifest, but sooner or later it makes trouble for the careless producer. With ordinary black bromide or P.O.P. it may be months, even years, before a general yellowing of the image or uneven patches begin to appear, but with sepia-toned bromides retribution is swift, for deterioration sets in before the work is finished, and sometimes the cause is not suspected, the paper, the bleaching solution, and even the sulphide bath being blamed, while the fault is due to improper washing. The great fact to be remembered is that Farmer's reducer is composed of ferricyanide and hypo, and that no matter in what form or for what purpose a solution containing these two chemicals is applied to a print the effect will be the same. We all know that when a print has been locally reduced the tone of the reduced part will be different from that of the remainder; sometimes only slightly and at others very noticeably. Now a very small

trace of hypo in a print is sufficient to react with the ferricyanide in the bleacher, and to start reduction of the image sometimes evenly and sometimes in patches or streaks. We have seen a batch of excellent prints which should have given excellent tones turn out a wretched ginger colour from this cause alone, and not only have the badly washed prints been affected, but properly washed ones have also been spoiled by the hypo conveyed into the bleacher by the former. Unless carefully watched many printers will trust to throwing prints into a large dish or sink and allowing a tap to run upon them, and if that tap runs for an hour they will say that the prints have been washed for that length of time. Failing a perfect mechanical washer there is no safe method of freeing prints from hypo except by hand washing, that is transferring the prints singly from one dish of water to another. Even as few as six changes of five minutes each in this way, provided that an ample quantity of water is used, will render prints safe for toning, and secure black ones from fading. There are two well-known tests for the presence of hypo, permanganate of potash and iodide of starch, and it would be well for anyone who is getting bad colours from apparently good black prints to apply one or the other. We know of one great firm which tests every batch of prints, bromide or gaslight, with permanganate, and the results are conspicuous for their good tone.

ECONOMY OF CHEMICALS.

WHEN we compare the present prices of nearly all chemicals with those ruling before the war we find that the increase in the year's expenditure in this direction is a serious matter, and as it is a matter of percentages as serious for the small user as for the large one, whether the expenditure be five pounds or five hundred, it is important that full value be obtained for it, and this can only be done by keeping a watchful eye upon every stage of the work.

Very often waste begins even before solutions are made up. This is usually due to the want of proper receptacles for the stock when it is delivered. Quite often chemicals, such as sulphite and carbonate of soda, alum, and even ferricyanide are purchased in paper packages of twenty-eight pounds or less, and taken into use at once without putting into proper jars, the parcels being laid upon any convenient shelf exposed to the air and dust, besides often being scattered upon the shelf or floor. It certainly should not be necessary to allude to such a state of things, but it undoubtedly exists in many places, and should be stopped without delay. Next to this is the practice of guessing at quantities when mixing solutions, for in this way a loss of 10 to 20 per cent. may easily occur, especially in the heavier kinds we have mentioned. It is not necessary to weigh most chemicals carefully as a system of dry measurement is usually sufficiently accurate, but it is desirable to keep in each jar or cask a measure which will hold what may be called the unit quantity, so that any boy or girl may be entrusted to make up the usual bulk of solution without supervision. Nearly everybody makes up certain quantities of solution at a time. To take the case, say, of pyro developer, the jars holding sulphite, carbonate, and metabisulphite should each contain a vessel such as a jam-pot or one of the cardboard canisters now commonly used, which when filled to the brim and struck off level will hold exactly the quantity required for a Winchester of solution. The card canisters are convenient, as they may be cut down to the right depth with a penknife. The pyro itself is usually supplied in ounce bottles, so that no measurement is needed, but if purchased in bulk in the crystal form it should also be measured, or, if in the old resublimed state, carefully weighed. This should be done not only as

a means to economy but also as tending to uniformity of result. The same system should be applied to other solutions, such as amidol, hydroquinone, and such things as reducers and intensifiers, the only exception being when the stock solutions are saturated ones. With amidol developer the practice of making a stock solution of sulphite and adding the dry amidol as needed is an especially wasteful one, as there is always the possibility of using more than is needed, and, moreover, neither the mixed developer nor the sulphite solution keep in working order so long. The better way is to make a fair quantity of solution at once with the addition of metabisulphite as a preservative. A good formula is two ounces of sulphite of soda and a drachm of metabisulphite dissolved in twenty ounces of water to which is added a quarter of an ounce of amidol. This is diluted with an equal bulk of water for use, and will keep in good order for a week or more. It is frequently the practice to throw away amidol solution which has been little used, and although we do not advocate overworking it, it has been found quite practicable to keep used developer over from day to day, adding fresh as needed. In one studio the amidol was kept in a jug after use, and only thrown away when the excess of bromide rendered it necessary. The prints produced by this procedure were as good as most that we have seen. In this case we may say that no bromide was used in making the original solution.

A very common cause of waste is to be found in a hurried, sloppy method of working, by which much solution is carried away upon the prints, *e.g.*, when removing enlargements from the fixing bath. If a print is lifted quickly out of the hypo quite an appreciable quantity is carried into the first washing water, and at the end of the day's work the bulk is seriously reduced. With hypo at six shillings a hundredweight this is a small matter; at sixty shillings it is not. Even more wasteful is this practice in sulphide toning. Some printers waste quite half of the costly bleacher in this way.

Those who still work the gelatino-chloride or P.O.P. printing will find that the Eastman system of allowing a definite quantity of gold to a certain number of prints a very economical way of working, practically all the gold being used. For the benefit of those unacquainted with the plan we may explain that if a grain of gold be allotted to each dozen cabinets for a purple tone, by diluting the solution a larger number may be toned to brown or still more to a reddish colour, all the prints being put in at once and allowed to remain until the bath is exhausted. This not only saves gold, but ensures even toning.

Using an excess of solution for any purpose is so obviously wasteful that it hardly needs mentioning, yet it is frequently done. We have often seen three times the necessary quantity of ferricyanide reducer made up for cleaning a few bromide prints, while pyro developer is often used in a too lavish manner, especially when concentrated stock solutions are used. It is false economy to stint the developer, and many poor negatives are the result, but many assistants habitually use twice as much or even more than is really necessary.

Although not strictly within our subject, the waste of bromide paper through careless cutting or tearing deserves a word. One often sees prints with a margin nearly half the area of the finished print. This is not only wasteful of paper, but of all the solutions used. Odd-shaped enlargements such as eleven by seven upon twelve by ten paper run away with a strip which if trimmed off before exposure would serve for tests or even for small prints. All these little things mount up in a year, and even if the exact amount saved cannot be calculated the profits will appear appreciably better. War-time orders are at an end now, and it is well to bear in mind the old proverb that a penny saved is a penny earned. There is another which says penny wise and pound foolish. The wise man will steer between these extremes.

PRACTICUS IN THE STUDIO.

ARTIFICIAL LIGHTING.

It seems only a few years ago that a photograph taken by artificial light was somewhat of a curiosity, and, with one or two brilliant exceptions, photographers were apt to regard it as a poor substitute for daylight, and, to tell the truth, the work generally produced quite justified their opinion. That I need hardly say was a time when electric mains were unknown, and the photographer who wanted to use the electric light had to instal an engine and dynamo in his cellar or else to burn "white fire" in a specially built lantern, the precursor of the modern flashlight. The plates were then much slower than modern ones and the candle-power of the light much less, so that there was a tendency to reduce diffusion to a minimum, and chalky faces and black shadows were the usual thing. I mention these old times because there are still many people who imagine that there must be something inherently different between a daylight negative and an artificially lighted one, and that the latter needs some sort of apology. This is quite a mistaken idea, and anyone who holds it should make up his mind so to improve his work that even an expert should not be able to tell the difference.

Before dealing with any of the types of installation which are now on the market, I should like to impress upon my readers that there is no essential difference between day and artificial lighting as far as effect is concerned—that is to say, that a top-

light will give sunken eyes and hollow cheeks, a low side light will give the contrary effect, that an unscreened light gives the effect of direct sunshine, and that a well-diffused electric light gives much the same effect as ordinary daylight. This gives the key to successful lighting, for if the operator will carefully note the position of his dominant light when using daylight he can produce practically the same effects with any other illuminant if he places it in the same position with relation to the sitter.

The most important problem is that of diffusion, or one might say distribution, of the light, and the difficulty is greater or less as the original source of light is small or large; a single pan arc is the most difficult to manage and a battery of half-watts or small enclosed arcs is the easiest. Still the single large enclosed arc is not to be despised; I never feel unhappy with one at my command, therefore I will start my detailed instructions with this instrument.

The enclosed arc is an ordinary single pair of carbons enclosed in a glass cylinder so as to be practically airtight. The effect of this is that a much longer arc can be maintained. A long arc emits more violet rays than a short one, consequently shorter exposures can be given. Incidentally there is less consumption of the carbons, so that the lamp does not require much attention. An ordinary street lighting arc

enclosed in a ventilated globe is classed as an open arc and must not be confused with the enclosed arc properly so called. The difference between the various types of enclosed arc lamps is in the feed mechanism only and not in the light: with a given diameter of carbons and quantity of current you will obtain the same amount of light if your cylinders are kept clean. I have worked continuously with the Westminster, Jandus, and Aristo lamps, and have found them all satisfactory. I think I have tried every reflecting and diffusing device on the market, and have come to the conclusion that the simpler the arrangement the better. My shade or diffuser—call it what you will—is made of two wooden hoops about 36 ins. across connected by four laths about 45 ins. long. Round these are bent thin cardboards so as to make a cylinder open at top and bottom with one-third left open. The inside of the card is covered with dead white paper (if white cards are used this is not necessary) and the outside with dark paper or cloth. The open third is now covered with tracing cloth, and the whole attached by cords to the chain or shackle from which the lamp hangs. It is a good plan to fasten the tracing cloth with push-pins so that it can be easily removed when the carbons have to be renewed or the glass cylinder cleaned. If possible the lamp and shade should be adjustable for height, so that it may be lowered for sitting figures and for children, it being always remembered that a foot or 18 ins. difference in position may mean 20 to 40 per cent. difference in exposure. With this shade I have found no other accessories necessary, beyond an ordinary round head screen, which I nearly always interpose about halfway between light and sitter, leaving the lower part of the figure unshaded, and the usual white reflector. I have sometimes hung a dark curtain or valance to the edge of the lamp-shade to avoid a glare into the lens, but this is not always necessary.

Open arc lamps are usually so fitted that only reflected light is used, the best known type, Marions Northlight, being very similar to the original Van der Weyde model, but fitted with several pairs of carbons to reduce exposure. The arcs are screened by a metal reflector on the sitter's side and the light reflected from the whitened inside of an umbrella about 4½ ft. in diameter. The surface of this may be regarded as a brightly lighted window, and any necessary diffusion provided for with the head screen already mentioned; the reflector is, of course, employed as needed. The highest type of work has been done with this system of lighting, the only drawbacks being a larger consumption of carbons and current than is necessary with the enclosed arc, while the large umbrella reflector takes up a good deal of space in a small studio.

Although there have been several other systems of arc lighting before the photographic public, the foregoing are practically the only survivors, and they will have a hard struggle for existence against the nitrogen-filled or "half-watt" lamps, which are making rapid headway as the simplest and least expensive of any system which has yet presented itself.

Before proceeding to these I should like to touch upon another form of electric lighting which has many good points: the mercury-vapour lamp. This is easy to manage, requiring no attention, and is economical of current, while owing to the large area over which the light is spread the lighting is fairly soft. Its one defect is its colour, which is greenish, and this gives anyone exposed to its rays a somewhat ghastly appearance. This can be overcome and the lighting improved by hanging a thin pink curtain in front of the tubes: this not only tones down the green but acts as a diffuser. As the tubes are somewhat long the lower part of the light tends to flatten the features somewhat, and I have found it advantageous to have the upright support lengthened, so that the bottom of the tubes are 4½ to 5 ft. from the floor. The tubes are rather fragile, so that care must be exercised in moving the apparatus about. Especial note must be taken of the connections, so that the polarity is never reversed, or disaster will follow.

It is easy to make such a mistake if a wall-plug is used, and some means should be taken to make it impossible to put the plug in the wrong way.

The half-watt lamp as made for photographic work closely resembles the ordinary metallic filament lamps used for domestic lighting, but is much larger than these usually are. Its distinctive feature is that instead of the interior being as nearly a vacuum as it is possible to get, it is filled with an inert gas such as nitrogen, which greatly retards the volatilisation of the filament when the lamp is run at a high voltage. Most people know that if a lamp be run at an appreciably higher voltage than it is made for the light is rendered much more brilliant, but that the life of the lamp is shortened to a few hours or even a few minutes. Owing to their construction the half-watt lamps have practically the same life as the ordinary type, while the light is rendered white enough to enable short exposures to be made in the studio. The General Electric Company has devoted considerable attention to the photographic aspect of half-watt lighting, and send out not only suitable bulbs, but reflectors and stands ready for studio use. I have worked with several installations of half-watt lamps, and can recommend them to any photographer requiring a new installation. The lamps are made in various candle-powers from 500 to 3,000. I prefer the 1,000 c.p. as the best unit. If six 1,000 c.p. lamps be taken as the maximum power needed for ordinary work, these can be so spread out as to cover a considerable area and to give sufficient softness with very little loss of light by diffusion. If two 3,000 c.p. lamps were installed they would be as powerful as two arcs, and would have to be placed farther from the sitter and a thicker diffuser would be needed. The metal reflectors supplied by the company are convenient and a great protection to the lamp, but I have found the light rather too concentrated, and have always fixed a thin white nainsook curtain in front of them. They can be fitted with a counterbalance weight like a grocer's scales, so that they may be raised or lowered to any desired height. A cheap method of fitting is to make large D-shaped reflectors of white card with a front of nainsook. The most useful size is about two feet wide by thirty inches high for the nainsook front, and eighteen inches deep from the centre of front to the back. One must be careful to place the lamp well in the centre, as there is a considerable amount of heat from the lamp, and if too near either lamp or calico one or the other will be burned. Light weight tinsplate can, of course, be substituted for the card for a permanent installation. I used the card lanterns for six months, and got one slight scorch only.

With regard to the arrangement of the lamps it is difficult to give precise instructions, and in accordance with my previous remark I recommend them to be placed so as to allow the light to fall upon the sitter at the same angle that daylight usually does. As it is undesirable to place them between the daylight and the sitter they should be placed on the dark side of the roof in the same position as the open portion of the light. If it be desired to light the same side of the face as with daylight the lamps should be placed towards the other end of the studio and the camera turned round. For average lighting the lamps should be fixed so as to rise to eight feet from the floor for standing figures and groups, and lower to about five feet six inches for sitting figures and children. The general arrangement may be in the form of a curve or L shape, one lamp being opposite the centre of the background and about seven feet away, another opposite the edge of the background and a little nearer to it, while two of the others are placed between these and two to serve as a side-light or for Rembrandt effects. Each lamp should be on a separate switch, so that only as many as may be necessary are burning at one time. It is very necessary that the exact voltage, not a nominal one, should be given when ordering lamps. Inquiry

should be made at the local power station, for a very slight drop in voltage means but little loss of light visually, but a great deal as regards the actinic value. In most cases where length of exposure has been complained of I have found this to be the cause. In districts where variations of current are common it would be well to use slightly lower voltage lamps than the nominal local voltage calls for, and to have the adjustable resistance supplied for these lamps and regulate the current as needed.

PRACTICUS.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications January 13 to 18:—

DARK-ROOM LAMP, No. 1,000.—Dark room lamp, which can be used as photographic printing apparatus. J. P. Hansen.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

COLOUR PHOTOGRAPHY.—No. 112,760 (January 15, 1917). The invention consists in a method of preparing three-colour composite photographs, in which one colour component is contained in one image and the other two distributed in a second mosaic image. The details contained in the specification are printed in another page in the "Colour Photography" Supplement. Hesse Ives Corporation, 1201, Race Street, Philadelphia, and Frederic Eugene Ives, 1327, Spruce Street, Philadelphia.

COLOUR PHOTOGRAPHY.—No. 121,776 (Dec. 15, 1917). The invention relates to a method of producing positive colour photographs by means of colour screens, and has for its object so to utilise a layer or film of white pigment placed on a multi-colour screen so as to imbibe from the latter colours required for the photograph.—HANS PEDERSEN, 3, Istedgade, Denmark.

[The subject-matter of this specification is printed on another page in the "Colour Photography Supplement."]

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SUNDAY, FEBRUARY 9.

United Stereoscopic Society. "Switzerland." A. T. Mole.

MONDAY, FEBRUARY 10.

Bradford Photographic Society. "Our Limestone Hills." R. Steele.

Dewsbury Photographic Society. "Photography and Art." E. R. Blakely.

TUESDAY, FEBRUARY 11.

Royal Photographic Society. Ordinary Meeting and Annual General Meeting Halifax Scientific Society (Photographic Section). "The Transposition of Colour into Monochrome." J. P. Oakes.

Hackney Photographic Society. Slide Competition.

Chelsea Photographic Society. Annual General Meeting.

Manchester Amateur Photographic Society. Monthly Meeting. "The Romance of an Old Canal." J. J. Phelps.

WEDNESDAY, FEBRUARY 12.

Croydon Camera Club. "Toning Bromide and Gauthi Prints." H. B. Newcombe.

Hford Photographic Society. "One Man Portfolio." R. Chalmers.

Deobolton Amateur Photographic Association. "Pictorial Principles and Practice." R. Wallace.

Photomicrographic Society. Members' Evening.

THURSDAY, FEBRUARY 13.

Liverpool Amateur Photographic Association. "War Chemistry." H. R. Jensen.

Brighouse Photographic Society. "Tips and Dodges for Pictorial Workers." F. Whitaker.

Hammermith (Hamphire) Hovell Photographic Society. "The Western Highlands of Scotland." J. A. Anderson.

Hull Photographic Society. Members' Home made Apparatus. L. Kirk.

Rodley and District Photographic Society. Lantern Evening.

Wimbledon Camera Club. "Oxford." A. H. Verstage.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, February 4, Mr. Charles Smith in the chair.

Mr. S. Gardner gave a very interesting lecture on "English

Fonts from Saxon Times to the Sixteenth Century." Mr. Gardner possesses a wide archaeological knowledge and argued out many disputative points connected with this subject.

An appreciative audience accorded the lecturer a hearty vote of thanks at the close of the meeting.

CROYDON CAMERA CLUB.

As the now Past President, Mr. A. F. Catharine, observed, "we come to another annual meeting after an interval of a year," which all will agree is hardly unusual. He retires, alleging that the reconstruction work of this country will unduly engage his attention. If he has undertaken the whole job, it will. The lofty traditions of the presidential office have been fully maintained by him, and aerated with a subtle humour. Mr. J. Keane again fills the post, and in expressing gratitude to his predecessor, fairly cleaned up the room with floods of oratory. Among other acknowledgments, the vote of thanks accorded the Council deserves mention, as it was passed in dead silence (out of respect). Fresh blood is added to more ancient gore, but not until fireproof paper is available to withstand the concentrated brilliancy can the components of the "Great Twelve" be resolved into a detailed list.

The Secretary, Mr. J. M. Sellors, to the great relief of all, continues to run the show, for certainly no better or a harder working secretary could be found. His report for the year showed everything on the up grade, including the rent. In customary slough-hound fashion he has managed to secure the new landlord as a "honorary member" at half-rates, the latter being one of those sensible individuals who take no interest in photography. He intimated his intention of attending the club at an early date, and doubtless will be carried out with all reverence. Deserves to be, anyway, for the club will be hard pushed to meet his modern views. The Treasurer, Mr. F. C. Reynolds, announced a profit of nearly £13 on the year's trading, and all wondered how it had been done, and who had been done. Mr. H. C. Inskip has been O.K. in the refreshment department, putting its customers in the best of spirits, and (with watery reservations) *vice versa*. The proceedings concluded with a discussion on a proposed new rule, debated in a style which would have made even a theological argument sound calm and charitable by comparison.

A word to the vivacious moralist who runs the "Imperial Notes." At convivial Croydon meetings the members throw at each other neither brickbats nor bottles, despite his suggestion to the contrary. Let him understand that roses, or other flowers according to season, are projected through the air. This gay and festive writer will be wise if he continues to expand on potatoes or what not (present plate prices alone excepted) as a fitting introduction to dry-plates, and leave the C.C. severely alone.

Commercial & Legal Intelligence.

PARTNERSHIPS DISSOLVED.—Notice is given of the dissolution of the following partnerships:—(1) Between Nellie Constance Baker and Gladys Methven Brownlee, carrying on business as photographers, at 18, Charlotte Street, Park Street, Bristol, under the style of Gladys Methven Brownlee. All debts due to and owing by the late firm will be received and paid by Gladys Methven Brownlee. (2) Between Phyllis Pullin and Llewellyn Johnson, carrying on business as picture framers, etc., at 125A, Abbey Street, Nuneaton, under the style of Pullin and Co. All debts due to and owing by the late firm will be received and paid by Llewellyn Johnson.

FORTHCOMING EXHIBITIONS.

February 10 to 22. Glasgow and West of Scotland Amateur Photographic Association Inter Club Exhibition. Secretary, Gilbert S. McVean, 125, West Regent Street, Glasgow.

February 20 to 22.—Leicester and Leicestershire Photographic Society. Secretary, H. C. Cross, 80, Harrow Road, Leicester.

February 22 to March 8.—Edinburgh Photographic Society. Entries close February 13. Secretary, George Massie, 10, Hart Street, Edinburgh.

News and Notes.

ROYAL PHOTOGRAPHIC SOCIETY.—The following have been elected to the Fellowship:—W. Foster Brigham, Frederick Humpherson, Norman Frederick Horne, James Henry Jennings, Floyd Vail.

ROYAL INSTITUTION. A general monthly meeting of the members of the Royal Institution was held on Monday afternoon, February 3. Sir James Crichton-Browne, M.D., I.L.D., F.R.S., treasurer and vice-president, in the chair. The Chairman reported a bequest of £300 from the late Dr. T. Lambert Mears, who was a member of the Institution for fifty-three years, and a donation of £50 from an old member in celebration of his fiftieth year of membership. Mr. A. J. Walter, K.C., was elected a manager to fill the vacancy caused by the death of Sir Charles Norris Nicholson, Bart., M.P.

EXPLOSION AT A PHOTOGRAPHER'S.—A gas explosion, by which a considerable amount of damage was done, occurred last week at a shop and house in Sangley Road, Catford, recently taken by Mr. William Craddock, photographic enlarger. While Mr. Craddock and the workmen were engaged on the ground floor an explosion took place between the shop and the floor. Fortunately Mr. Craddock's wife and two children were away at a neighbouring picture palace at the time, and no injuries were sustained by the occupants of the place. Two windows were blown out, several ceilings were brought down, and the shop and house of seven rooms were damaged.

DIFFICULTIES OF PHOTOGRAPHY IN BELFAST.—Although Belfast professionals managed to keep the flag flying last week it was, in most cases, in spite of unprecedented difficulties. The inconvenience of having no gas or electricity was added to by a coal shortage and an absence of lamp oil and candles, this latter being brought about by the general rush. A wintry daylight was made as much use of as possible, in one case being requisitioned to serve a "Pawl" strip printer! So far photographic premises have been fairly lucky in escaping the attentions of the crowd, though the iron gate posts outside Messrs. Thompson's studio were annexed while the caretaker was tied up, and the plate-glass window of Mr. J. Bell's establishment was smashed. Up to Saturday night there was no sign of better conditions.

SOCIETY OF MASTER PHOTOGRAPHERS (Lancashire and District).—The Society will hold its first annual dinner on Tuesday, February 25, in Manchester. The officers and committee trust that all the members will do their utmost to make this function a big success. The price for tickets has been fixed at 7s. 6d. each. Ladies are cordially invited. Detailed arrangements are not yet completed, but it is essential that all who intend to be present should notify the Hon. Sec. before Monday, February 10. An exhibition of members' work will be held in Blackpool on Tuesday, May 27, 1919. A cordial invitation is also extended to all members of the P.P.A. who can make it convenient to attend on that date. Full details of the exhibition will be sent out by circular to every member in due course. The Sub-Committee appointed, Messrs. Bayliss, Foley, and Huish, together with the officers, will be grateful for any helpful suggestions and ideas for the exhibition, which may be forwarded to the Hon. Sec., F. Read, 14, Balfour Road, Southport.

S.P.E.S. TRADE-MARK.—A copy of the regulations under which it is proposed by the Swiss Chambers of Commerce to establish a Swiss national trade-mark under the name of S.P.E.S. (Syndicat pour l'Exportation Suisse) discloses the fact that the mark will be confined to firms two-thirds of whose capital is Swiss, and to goods that are made in Switzerland exclusively by the Swiss. Thus any foreigners manufacturing in Switzerland will not be able to use the trade mark for goods manufactured by them. The object of the trade mark, it is stated, is not to place foreigners at a disadvantage, but to ensure that any articles bearing S.P.E.S. are to be really of Swiss manufacture. In addition, the mark is directed against German penetration, as numerous firms are known to be ostensibly Swiss, but in reality are German. The president of the Geneva Chamber of Commerce states that the control of these will not be easy, but the committee is alive to the probability of

the improper use of the mark, and they consider that it will be necessary for Swiss manufacturers to bring cases of this character to official notice. No foreign firms are to be prevented from manufacturing in Switzerland; but not being Swiss, they are to be debarred from using the trade-mark. With regard to the possibility of the extensive misuse of the trade-mark by exporting merchants, it may be necessary to add the manufacturers' name to the trade-mark. This may not be acceptable to exporters, and if the suggested trade-mark fails, as a result, to protect Swiss manufacturers, it is considered probable that the Chambers of Commerce concerned will propose its abolition.

Correspondence.

. Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

. We do not undertake responsibility for the opinions expressed by our correspondents.

A CORRECTION.

To the Editors.

Gentlemen,—Will you kindly afford me the space to correct an error that occurs in the report of the last Council meeting of the P.P.A. in your January 31 issue. In reference to the Government demobilisation scheme it is printed that the scheme afforded an opportunity for the Association to do more to secure release than could be done by the man himself. It should be no opportunity. —I am, etc.,

ALEXANDER MACKIE, Hon. Secretary.

89, Albany Street, February 1, 1919.

PURPLE TONES ON BROMIDE.

To the Editors.

Gentlemen,—On reading your reply to "R. M." in "Answers to Correspondents," I gather that he or she was inquiring for a purple tone on bromide paper.

The formula given below will give an excellent purple tone on any make of bromide paper, which is equal if not better than any gold-toned P.O.P. or self-toning paper. Thorough washing after each operation is required.

Bleach in:—

Potass. ferricyanide	140 grs.
Ammonium bromide	180 grs.
Water to make	10 ozs.

Wash and re-develop in:—

A.—Hydroquinone	170 grs.
Potass. metabisulphite	90 grs.
Potass. bromide	20 grs.
Water to	10 ozs.
B.—Ammonium carbonate	1 oz.
Water	10 ozs.

Equal parts of A and B.

Perhaps this might be useful to your readers.—Yours,

E. MANLEY.

Earlwood, Hockley Heath.

ARE MATERIALS PRICES TO FALL SOON?

To the Editors.

Gentlemen,—Your correspondent Mr. H. Green, in his "Writing on the Wall" predictions, *re* the fall in prices, is fully entitled to the optimistic views he sets forth, but the chuckle at the withdrawal of Government contracts from the photographic houses may be premature if he looks for an early fall. He admits he has never marvelled at the great increase in prices, and by that I conclude he understands something of the laws of supply and demand and its natural effect on prices. If he is a professional he has not suffered on returns compared to pre-war days, and has no legitimate grievance. With the release of raw materials there are prospects of a fall in price, and the trade helps the buyer in this respect by accepting orders subject to ruling price at time of

despatch. "As a "Man of the Road" one acquires certain characteristics, serious or jocular, each with his own particular style of selling talk. The representative of a first-class house with a full knowledge of the lines he is offering is more often welcomed and consulted than looked upon in the light suggested by Mr. H. Green. The writer is not given to begging or praying for orders; these come naturally through carrying the lines of our leading manufacturers, and the men carrying these not only build up their connections on the merit of those goods, but add laurels to their own personality.

15, Hillcrest Road, Acton Hill, W.3.

HARRY HUNT.

THE ASSISTANT QUESTION.

To the Editors.

Gentlemen,—I feel sure all the parties interested in the Assistants question will agree that you deserve much praise and many thanks for allowing the interesting letters on the above question to be published week by week. It's a very important matter, so should deeply concern everybody engaged in the profession, but many do not seem to realise to what extent it does influence their interest.

We are still open for suggestions and opinions. I have much more to express, but will leave it to a later date when all have spoken.

Again thanking you, yours very sincerely,

MARCUS ADAMS.

To the Editors.

Gentlemen,—I have been interested in the correspondence on the Assistant question in your columns, although I am sorry that I missed Mr. Adams's original letter, from which I believe it arose. I am rather sorry to gather from Mr. Adams's letter in your last week's issue that he is afraid that he cannot see his way to taking the matter up in a practical form at the present time, as in many respects it would seem a particularly favourable opportunity for dealing with a question of this sort, owing to the numerous changes which are taking place in the staff of photographic businesses as demobilisation proceeds.

Having frequent occasion to engage assistants, I have been impressed with the difficulty of obtaining really competent workers in any department, and with the entire absence of any definite standard of attainment.

I think this is no doubt due to the unsatisfactory system of training assistants, and to the almost entire absence of any facilities for technical education in photographic processes leading to a certificate of ability, such as exist, at all events, to a greater extent in some kindred industries.

So many photographers have taken up the business without any thorough knowledge or experience themselves that they are absolutely unfitted to train others, and when they take pupils or apprentices look on them, I am afraid, more as a means of obtaining cheap labour, and fail to realise their responsibility to give them a good training.

On the other hand, in larger and more efficiently managed businesses the work tends to become so specialised that it is very difficult for a learner to acquire a knowledge of more than one branch, and even then only the more mechanical part of the work.

He is greatly dependent on the willingness of the head of his department to impart more instruction than is absolutely necessary to enable him to carry out his more or less mechanical duties.

I think if the P.P.A. seriously took up the question of proper training and certification of photographic assistants in the various branches of modern photographic work they would be conferring an immense boon on the industry as a whole, and would gradually raise the whole status of the photographic profession, to the benefit not only of the assistants themselves but also to all employers.

So many employers appear to adopt what seems to me a short-sighted policy of paying the minimum wage, and offer so little inducement to their assistants to improve their position, that many, who might otherwise have been content to remain on the staff, are tempted to start in business for themselves, with inadequate capital and little or no business experience.

This almost inevitably leads to price cutting and other unsatisfac-

tory competitive methods, which, while seldom providing them with a satisfactory income, must, to some extent, detract from older established businesses.

Hoping this matter will be taken up in earnest, yours faithfully,

G. E. Houghton.

55, Fort Road, Margate, January 30.

To the Editors.

Gentlemen,—Having followed the present and previous correspondence on this matter, I am surprised at the lack of suggestions, practical or otherwise. If the following remarks of mine call forth a chorus of disapproval, the air will have been cleared a little and we shall be able to dispense with one idea of solving this problem. At the same time it may be of some practical use in assisting Mr. Marcus Adams to gauge the temper of those whom he is trying to help.

As an assistant, I have no sympathy with an assistants' union as opposed to any employers' association. I will not reiterate old, or introduce new, arguments here. That does not mean I do not wish to tackle them. I could do so later if necessary.

Very skilfully hidden away in Mr. Frank Brown's letter was the one vital point upon which so much depends, i.e., efficiency. This point needs very much consideration, and before any clear idea of what constitutes an efficient assistant can be determined, an acceptable standard definition must be adopted. That definition should be discussed, decided and published by the P.P.A. as early as possible. Each branch of assistants should be classified and with it the degree of skill required. Assistants not having attained that standard should rank as improvers or unskilled until they do attain it.

My proposition is:

(1) That the P.P.A. should be a professional photographers' association and not an employers' association only. All photographers to be admitted to membership on payment of subscription and be duly registered.

(2) That the employers' council remain as it is and continue to conduct all business matters.

(3) In addition, a secretarial office be established to collect and tabulate (a) all photographic employers, hours, class of work; (b) all photographic assistants, their branch and references; (c) all written general grievances and opinions for use of general secretary; (d) all available information relative to photography, including books and where obtainable; also the addresses of technical schools useful to photographers. Such information to be supplied to any member on request.

(4) The general secretary should attend the employers' council monthly for the purpose of laying before that body the general grievances and opinions as collected in the secretarial office. A full report of such meeting to be published in the B.J.P., or circulated in leaflet among the P.P.A. membership.

(5) Cases of individual grievances, as unfair dismissal, leaving without due notice, or any breach of contract, should be referred to the solicitors for the P.P.A. In all such cases these solicitors shall conduct the proceedings for the P.P.A. against the employer or assistant offending.

(6) All binding contracts between employer and assistant to be made through the solicitors above.

(7) The test of ability for an assistant should be his references. A new reference, when proved satisfactory to those concerned, to be signed by the general secretary and duly recorded in the secretarial office. Any dispute concerning the withholding of a reference, or the untrue or unsatisfactory nature thereof, to be referred to the solicitors above.

(8) The employers' council be invited to discuss and fix a schedule of minimum wages for each branch of assistants, and a copy of the schedule sent to every member of the P.P.A. and comments and suggestions invited. The schedule to be subject to further discussion and possibly amendment when the general secretary has collected the opinion of the majority on its merits.

These brief suggestions will, I trust, bring a new interest into this correspondence, and open out some of the tracks which have hitherto been unexplored. I am, sirs, yours truly,

ROWLAND SAMMES.

Reigate, February 4, 1919.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed (see reply: 5-cent. International Coupon, from readers abroad).

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

A. C.—The apparatus is supplied by Messrs. Walshams, Ltd., 60, Doughty Street, London, W.1.

S. B.—The material you require is sold by G. Palmer, 47, Gerrard Street, W., and Messrs. F. Wiggin and Son, 102-4, Minories, E.

R. K.—The Busch *f*. 5.5 anastigmat was listed at £14 10s., and its present value we should say would be at least half that price. But you will be well advised to try the lens before actually purchasing it.

Q. V.—Old studio cameras are not of much value, and we cannot, of course, give any idea of what yours is worth from the description you give, probably £2 to £2 10s. would be a fair price. The lens is by a good maker, but not of great repute in this country. It should fetch from £3 to £4.

P. M.—The spots may be due to particles of iron in the washing water, although when so caused they are usually blue. Try tying a piece of thin, close flannel or double calico over your taps. We note several spots on the unprinted piece of paper you sent, and have marked them. You might try making a print or two in another room where no chemicals are about; this may give a further clue. Do you mix chemicals in your dark-room?

B. O.—For the colouring of bromide prints and enlargements as it is professionally done by photographers there is no better book than Johnson's "Retouching," sold by our own publishers, price 3s. 4d. post free. There is no book specially on the colouring of miniatures with a photographic base, but Messrs. Winsor and Newton, Ltd., 37, Rathbone Place, Oxford Street, London, W.1, have a book on miniature painting which we should think would be what you want.

J. D.—We do not know what is added to ordinary flash-powders in the process of making those sold specially for Autochrome work, but the usual ingredients are barium fluoride or calcium fluoride, copper fluoride, and lithium fluoride. It is suggested that by suitable mixture of flash-powders containing these substances three-colour exposures may be made on panchromatic plates without a light-filter, but we should think that what is most probably done is that a certain proportion of barium nitrate is added to ordinary flash-powder and the lens provided with a compensating filter suitable for it.

T. W.—The Photostat apparatus, supplied by Messrs. F. W. Herbert, Ltd., Coventry, at prices ranging from £100 upwards, is a large installation for the rapid copying of documents. The latter are laid flat on an easel underneath a sheet of plate-glass, the lens, pointing horizontally above them, being supplied with a prism. The negatives are made on a special rapid colour-sensitive paper, a roll of which is held in a holder, and a portion which has just been exposed delivered by light-excluding mechanism into the developer. It is then taken out in ordinary dull light and put into the fixing solution.

E. R.—We are sorry that we cannot tell you of any absolutely safe method of packing framed pictures except in wooden cases. We have, however, received several safely packed between grids of thin wooden battens with thick paper inside and out. Per-

haps the makers of stretchers could supply these, or you could make them for yourself. To avoid breakage by shock it is a good plan to paste cross strips of brown paper three or four inches wide upon the surface of the glass, from corner to corner. If common paste or dextrine mountant be used, either can be easily removed by damping. A starch paste should not be used, as it is difficult to remove when once dried.

W. D.—Much depends upon the colour of the walls of the two rooms, but if they are fairly light we should say that about ¼-oz. of powder if quite freshly mixed should be enough for the dinner and 2 ozs. for the ball. One hundred and twenty ft. is a long way for the light to travel, and with a less quantity only the nearer figures would get enough exposure. This is reckoning for the *f*/11, with which you ought to be able to manage. As you will have to look down you can swing out the top of the camera back, and this should bring the near and distant planes into focus at the same time. Be very careful in firing the flash that no curtains or inflammable matter is near it.

B. E.—The plates, which are of American manufacture, were largely sold by Messrs. Fallowfield, 146, Charing Cross Road, London, W.C.2, before the war, but we are unable to say whether the firm are still able to supply. The only developer-formulae we know is that which appeared in the 1914 Almanac, and is as follows:—

Soda sulphite, cryst.	31 parts
Hypo	248 "
Soda carbonate, cryst.	8 "
Potass. bromide	8 "
Water	800 "
Hydroquinone	20 "
Ammonia (sp. gr. 9,891)	45 "

C. T.—1. There is no absolute reason why bromide should be used in a tank developer, though most people find that a little, say, ¼ grain per ounce of developer, is an advantage in safeguarding plates from veil. 2. As a rule, halving the amount of water in which the chemicals are dissolved will approximately halve the time of development. 3. In order to make the iodine solution dissolve the iodide in just as much water as will cover the crystals and then add the iodine, afterwards diluting to the bulk required with water. 4. The sensitiveness of the Ilford new panchromatic plates is such that they can be used with very great advantage without a screen. The Autochrome screen is quite unsuitable for them, but the "Ensign" screen might be used, although the best screens for use with panchromatic plates are the "K" series of Messrs. Wratten.

SUMMARY.

A paper on panoramic perspective, dealing with the arrangement of groups taken with such cameras as the Cirkut with a view to obtaining a straight-line rendering of a composition arranged diagonally to the camera, with the necessary diagrams, will be found on page 67.

In a leading article we deal with the moral effect upon the sinner of the appearance of premises and personnel of photographic establishments. (P. 66.)

A long interview with a prominent American pictorialist, Mr. Clarence H. White, in which he gives his views on the progress of pictorial photography in the United States, is reprinted on page 72.

A brief review of the various processes now available for printing from portrait negatives forms the subject of the "Practical" article on page 70.

A suggestion for obtaining orders from large size negatives by showing reduced proofs from them is made in an American contemporary. When plate prices drop, some of our readers may perhaps adopt it. (P. 75.)

The temporary loss of memoranda which need immediate attention is a source of annoyance in many businesses. We describe a simple method of keeping such papers before the eye on page 65.

Developer poisoning, print washing, the assistant question, and the mercury-vapour light in portraiture form the subject of letters on page 79.

Many photographers consider amidol to be the one and only developer for bromide prints, but the claims to consideration of metol and hydroquinone are put forward with some cogency on page 75.

A warning to those who may be tempted to buy lenses at private auction sales is given on page 66.

Lens matters, line drawings from bromides, Autochrome work, and dry-mounters are with many others dealt with in "Answers to Correspondents." (P. 79.)

It is difficult to say anything new respecting home portraiture, but in the report of Mr. Foster Brigham's lecture before the Royal Photographic Society the subject is handled in a novel way. (P. 71.)

The removal of silver stains caused by incomplete fixation or damp sensitized papers is a subject of perennial interest. We give some notes on it on page 65.

An almost automatic outfit for taking identification portraits for factory passes, railway tickets, and the like is illustrated and described on page 76.

A list of the officers elected at the annual general meeting of the Royal Photographic Society will be found on page 76.

EX CATHEDRA.

Stained Negatives. We suppose that by far the greater majority of stained negatives which are sent to us for a diagnosis of the defect represent the result of incomplete fixation. Unfortunately a remedy for the brownish stain which is the product of insufficient treatment of the emulsion with hypo is an almost hopeless problem in comparison with such general stain which comes from development or even the patchy stains due to contact with a printing paper containing soluble silver. About the only suggestion which we can make for the removal or, at any rate, partial remedy of fixation stains is to intensify the negative with mercury and ammonia, or with Monckhoven's formula of mercury and silver cyanide. By either of these processes the yellowish stain is converted into a grey one of little printing value, and with the aid of a certain amount of local reduction of the intensified negative it is possible in some cases to arrive at a respectable result, but whenever circumstances permit of a second exposure being made, the making of another negative is the only remedy which should be thought of. The silver stains from damp paper are of rarer occurrence in these days of development papers, yet it may be added that a ready means of removing them is that of Mr. Harold Baker, of rubbing with Globe metal polish and then leaving for a sufficient time in a strong solution of hypo. This is a very much better and safer plan than the iodide and cyanide method, the drawback of which is that the solution attacks the image proper as well as the deposit of silver stain, and therefore calls for an exceptional degree of expertness in its application.

* * *

A Business Accessory. "A place for everything and everything in its place" is one of those maxims of our childhood on which too much importance cannot be laid in any business establishment. The waste of time and the mental irritation which arise from the inability to find something which "you know is there all the time" and is only hiding itself through some diabolical malice, are elements which one tries to eliminate from the day's work. Partitioning of drawers and cupboards and a system of labelling the places where articles in frequent use are to be put when they are finished with will go far to removing these causes of reduced output in the normal working hours. But the suggestion we have to make—and it is one of which we have proved the utility—relates to a means for preventing the straying of the odd messages and memoranda which are part of the machinery of any business. It is simply a place where notes that such-and-such an order is wanted urgently, or such-and-such a chemical is getting out of stock may be placed so that they cannot be overlooked; where, in fact, which is the important

thing, they will be looked for. In our own office routine, which calls for many reminders, this takes the form of a good sized board covered with soft cork lino and provided with a supply of push pins. These serve to fix in an instant any memorandum which needs to be displayed to view until it is dealt with. The board speedily becomes an institution to which one looks and which soon largely replaces verbal messages. It seems to us that good use could be made of one or two of these devices in businesses, such as that of photographic portraiture, where there is much reference from department to department.

* * *

Photographic Apparatus at Auction Sales. A short time ago we commented upon the advisability of intending purchasers of second-hand lenses being very careful to see that the lens offered to them in a certain mount was actually the instrument issued new by a particular maker. We recently heard of an experience in connection with lenses which goes far to point out the importance of the buyer knowing fully what he is purchasing. The case in point was an auction sale, and among other things, household furniture, etc., two lenses by a well-known maker were catalogued. A photographer whom we know attended the sale, and after having previously examined the two instruments to his satisfaction, though he was not acquainted with the particular type of lens, bid for and purchased them for what was a fair sum. Of course, a trial upon a camera was not permissible, and his surprise may be judged when upon testing one of the instruments very indifferent definition was given. At some trouble the photographer got a catalogue illustration by the makers of the lens, and upon comparing the plan with his own instrument he found to his surprise that one of the components of the original instrument was absent altogether, which fact was made all the worse because the maker had long ago suspended business. And at a time like the present no others would be likely to take on such a job as supplying the missing component, even supposing such a thing was possible. This note is penned as a warning against those who may be tempted to buy photographic goods at general auction sales, which do not admit of a proper trial of the instruments catalogued. Such may turn out the reverse of a bargain, and as a general rule the purchaser has no redress, since most auctioneers in their conditions of sale hold themselves under no guarantee against errors of description.

* * *

A Home-Made Camera Case. Now that any goods of leather are so expensive it may be of service to some if we refer to a case for the camera outfit which we saw the other day for the making of which the photographer had used a substitute for leather which yielded a solid and yet slightly lighter case than that material. The case was made of ordinary three-ply wood, with a division for the slides, and the lid was fitted with lap-over edges in the same way as the best leather cases are made. The inside may be lined with thick green baize or thin felt, obtained from any upholsterer in a large way of business, and fastened with small gimp pins obtainable from the same source. The outside of the case was finished with a covering of good waterproof canvas fixed in position with dextrine paste, obtainable at any shoe or leather sellers, the edges of the canvas being turned over and fixed in position with the gimp pins before mentioned. To the bottom, four "Doines of Silence" furniture castors were fitted to keep the case off the ground, and so to reduce damage by its being placed for any time on wet ground. The case was made for less than a quarter the cost of one in solid leather, and weighs a few ounces lighter than

leather case of the same size. Provided the joints are firmly screwed there is nothing to fear on the score of solidity. Moreover, such a case allows a more substantial lock and hasp to be fitted than if the article were made of the ordinary stout leather.

APPEARANCES.

SOME people say that "appearances are deceptive," and others that "the first impression is everything." Although these dicta are apparently contradictory, there is truth in both, and our present object is to point out how outward appearances react on the success of a photographic business.

In photography more than in most businesses the impression made upon a prospective sitter is of the greatest importance. A shabby exterior, a dark and uninviting approach, or a dingy, untidy reception-room will probably act as a deterrent to the better-paying class of customers. The visitor will go no further than to make an inquiry as to prices, and retire as quickly as possible. This fact is more readily realised by women than by men, and may account for the fact that many women have started successful studios, while men who could turn out better work have failed to attract patronage. To the woman the trimmings are of primary importance, and she starts fitting-up her premises with much the same idea that she has in furnishing a home—that is, to make it an attraction to others and a source of modest pride to herself. Now it is not necessary to go to work in an expensive manner to achieve this end; the only thing necessary is to start with some definite scheme, and to keep it in view throughout. As the first contact with the public is usually by means of the showcase or window, we must start with that, and endeavour to make it as bright and attractive as possible, and always keep it so. Many places have been opened with an imposing array of plush and gilding, which for lack of care has in a few months become faded and dingy, giving the impression that no business is being done; while others started on more simple lines have by constant change and scrupulous cleanliness continued to attract the favourable notice of passers-by. Supposing that we succeed in doing this, the entrance and staircase, where there is one, should be respectable and well cared for. Dirty walls, with the paint or paper peeling off, worn linoleum, and dirty windows do not lead people to expect clean, artistic work behind them. This can all be remedied at small cost, and should at once be done where such a state of affairs exists. Many old-established photographers have experienced a serious drop in their takings when a rival concern has opened near them, not because the work was better, nor even as good, but because it was put forward in a more attractive way.

The reception-room is often allowed to degenerate into a sort of rubbish store. Obsolete furniture from the studio, parcels received or ready for despatch, frames, and out-of-date specimens cover the tables and chairs and utterly destroy that appearance of daintiness and comfort which is so necessary to the production of a complaisant mood on the part of the visitor. One old photographer always called his reception-room the drawing-room, and always kept it quite free from business lumber. Even his specimens were kept out of sight until they were required, the comfort of his patrons being apparently his sole aim. Others have made their reception-rooms interesting and profitable by displaying paintings, rare furniture, and curios, which not only served to pass the time while waiting, but which were ultimately sold. While on this subject it may be worth pointing out that the personal appearance of the proprietor and his

staff should be as carefully looked to as the other decorative items. Photographers used to have a reputation for slovenliness, and it is to be feared that some still merit it. They should take a lesson from the jeweller and other tradesmen who have to deal with ladies, and not appear in frayed, chemical-stained habiliments, while their assistants should be trained to those habits of neatness in dress and person which are expected to be found in a good-class business. One lady photographer insists on a uniform style of dress on the part of her receptionists, but this is going a little too far. Still, it is better than a tawdry blouse and a faded alpaca apron, which have been seen in studios of some pretensions.

The studio is a workroom, and need only be kept scrupulously clean and free from unnecessary lumber. The camera and stand should be kept well polished even if of old pattern, and anything in the way of greasiness on the furniture avoided. Velvet and leather chair-seats need keeping in order, as a lady does not like to risk soiling a nice dress. We have seen a lady refuse to sit on a greasy-looking chair, while others doubtless shuddered when they did so. The fittings of the dressing-rooms should be inspected daily, combs and brushes frequently washed, and a white druggist kept ready for use for wedding and evening-dress sitters. If powder and cosmetics are furnished, the pots and bottles should be kept free from smears and dust; actresses may tolerate dirty "make-up," private sitters will not. Nothing succeeds like success, and if trade is quiet the world must never know, for people like to feel that they are patronising a fashionable establishment, even if they have to wait for their portraits. One of the most successful American

portraitists has told how at the beginning of his career he found sitters were not so numerous as he had hoped for, so resolved upon a bold stroke. He filled his diary with imaginary appointments for a fortnight ahead, and declined sitters who would not wait for a vacant date. At the end of the period he had booked more genuine appointments than he had ever done before, and since then he has never looked back. When anything is difficult to obtain people are sure to want it, and when the sitters who had booked told their friends how terribly busy Mr. So-and-so was, they immediately felt that he was the right man to go to. Few British photographers would care to take such a risk as our American friend did, but it is well to keep up the impression that business is flourishing, and that it is only as a special favour that early delivery can be promised.

One little matter must not be overlooked, that of stationery. We receive many letters upon notepaper the quality and printing of which would disgrace a chandler's shop. When people contemplate patronising a self-styled artist they are apt to judge his artistic skill by the style of the communications he sends to them, and nothing is so detrimental as poor stationery. We do not advocate florid designs or bizarre colouring—the simpler the better—but the type should be artistic and the paper as good as we can get in these times. The money so spent will not be wasted. It is only invested, and will return increased a hundredfold before many days. The whole point is this—that the photographer must appear to have some self-esteem and confidence before he can expect the public to trust him, and therefore should make as good an all-round show as circumstances permit.

PANORAMIC PHOTOGRAPHS AND PERSPECTIVE.

THE notes on panoramic photographs in a recent number of the "B.J." will no doubt have interested quite a fair proportion of readers; and in all probability many more will welcome some amplification of the subject. And as there appears to be very little literature on this fascinating phase of the photographer's art, the following notes are penned with the hope they may at least help the novice, even if they fail in the more ambitious desire to stimulate the production of a scientific treatise on the principles involved. The panoramic camera is a necessity: there can be no question of that, and although much good work can be done by joining up several ordinary photographs, there are cases where all the skill in the world will fail to make a presentable picture; and an example of this failure occurs when we have a view including railway lines in the foreground. At each join the lines meet at an angle; and as we are not accustomed to trains tracing pentagons and squares, we are offended by the view. In a panoramic picture of the same subject, the lines will appear as continuous curves; so we are not asked to imagine the impossible, and therefore the eye and sense are not offended. To the professional mind, no doubt, the big group is the most important class of work to which this camera can be put, and here it so clearly scores that no argument is needed. These groups, of course, are arranged in an arc of a circle with the camera at the centre; and the general perspective of the resulting picture may be likened to one taken with an ordinary camera and a very long focus lens whose axis is at right angles to the same group arranged in a straight line. Now, whatever carping critics may say, the man at the end of a panoramic group will be far better pleased than if it had been a wide-angle group; for he is in the same perspective as

the man in the middle; and this will prove a blessing to the photographer who has to copy a single figure from a group for the purpose of enlargement, and alas! in very many cases, the only available source will be from one of those big military panoramic groups, and whatever consolation father, mother, or sister can get from the finished enlargement, it will be all the greater from the fact that their departed hero is delineated in true perspective, which would not be the case if the figure were copied from near the end of a wide-angle group.

The thing that is most objectionable about a panoramic view is when something that we know must necessarily be straight comes out in the photograph as a pronounced curve. There are two ways to avoid this: one is by the arrangement of the subject, as in the case of a group, or by the selection of the point of view. Now, in general, a horizontal straight line, except when it radiates from the camera, appears in a panoramic photograph as a curve; and, conversely, there is a certain curve which, when in a horizontal plane with the camera at its origin, will always appear as a horizontal straight line; and if we know the nature of this curve, we shall be in a better position to order the arrangements for any particular photograph we wish to take.

Let us take a practical example:—Fig. 1 is a diagrammatic view of Ludendorff, on horseback, giving a farewell address to his troops; and perhaps adding a few words of advice and warning on the disastrous consequences of a complication of Prussian macrocephalism and Asiatic heri-heri. In the ordinary panoramic parade photograph the men dwindle away towards each end of the picture, and form a strange curve that would remind a soldier more of some lamentable struggle

with the theory of a trajectory than of invincible, vandalic, martial glory and also it offends all our ideas of perspective. And besides, perhaps, Ludendorff would not like it; he might think you were poking fun at him, and intended some sly allusion to "elastic fronts." The remedy is to get the valiant soldier to let you arrange the men; and to get this effect of straight lines vanishing to the horizon, as in Fig. 1, they will have to be arranged in the form shown in plan by

that is to say, if three inches at the end of a Panoram represents 15 degrees, then also three inches from the middle will represent exactly the same angle, and if the line BO, joining the men's feet in Fig. 1, is to be straight, the vertical distance between it and HO must diminish by the same arithmetical amount for each equal length of the picture; and as the distances from the camera must be inversely as the height of the figures, we have the clue to every point of the

Fig. 1.

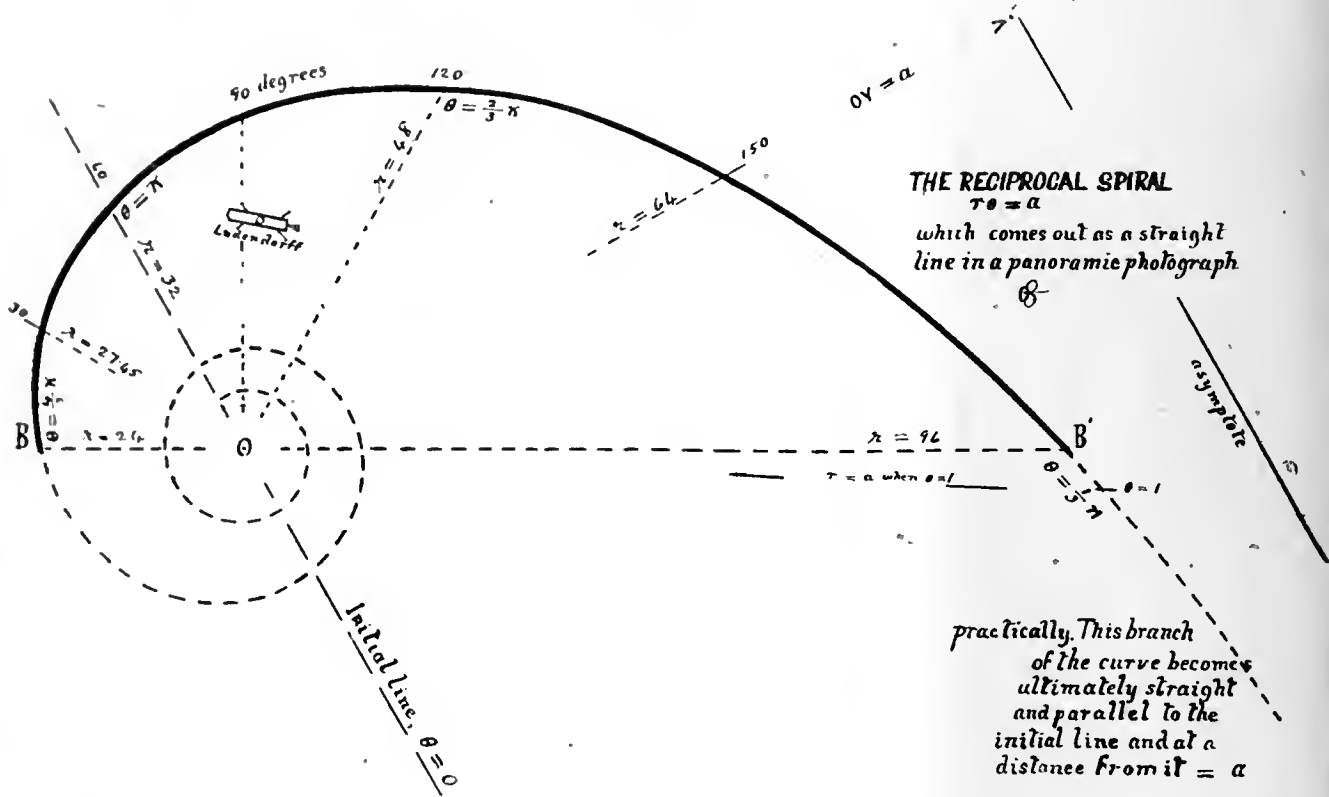

Fig. 2.

the heavy line in Fig. 2. If we are using a 12-in. lens, and decide to have the finished picture about 40 inches long, the group will have to be included in an angle of about 180 degrees; because $12\pi = 37\frac{1}{2}$ nearly, which will allow just a little margin each end. If we further decide that the nearest 6-ft. soldier shall be three inches high in the photograph, and the one at the remote end of the line one-quarter that height, then, by the simplest arithmetic, the nearest man must be 24 feet from the camera, and the furthest one 96 feet; and, as the group is to include 180 degrees, these two men and the camera will be all on the same straight line. This is shown to scale in Fig. 2, where the position of the camera is given by o, and B and B' are the places of the end men. The setting out of the rest of the curve is quite simple if we remember that the panoramic projection of the horizon is a straight line, and every length of a panoramic photograph represents an equal angle or number of degrees;

curve. Now, let us calculate the distance of the curve from the origin o for every 30 degrees. As the total fall in height is to be $3 - \frac{3}{4}$, and 30 is contained six times in 180, then

$$\frac{3 - \frac{3}{4}}{6} = \frac{3}{8} \text{ inch}$$

is the amount required; and in the table below the distances of the points are given in feet for every 30 degrees, while the heights of the image are given in eighths-of-an-inch, to avoid fractions and show better the regular decrease.

Degrees from point B.	Height of image.	Distance in feet.
0	24	$24 \times 1 = 24$
30	21	$24 \times \frac{7}{8} = 27.45$
60	18	$24 \times \frac{3}{4} = 32$
90	15	$24 \times \frac{5}{8} = 38.4$
120	12	$24 \times \frac{3}{4} = 48$
150	9	$24 \times \frac{3}{8} = 64$
180	6	$24 \times \frac{1}{4} = 96$

In regard to this table it may be observed that the product of the height and distance is a constant quantity. A group arranged in this way will, in the resulting Panoram, have the same general perspective as Fig. 1, though, of course, each element of the picture will have the perspective peculiar to the lens with which it was taken.

Now, if the lines AO and BO are continued they will meet outside the picture, at the vanishing point O on the horizon; and if we call the vertical distance between A and B h and the number of degrees from H to O α , which in this case will be 240 deg., then for every degree the height will decrease by $\frac{h}{\alpha}$; therefore, at any angle β , measuring from H, the height of the figures will be:—

$$h\beta = h \frac{\alpha - \beta}{\alpha}$$

and the distance from the camera to the curve at this point will be:—

$$r\beta = \frac{ra}{\alpha - \beta}$$

It will be seen that ra is a constant quantity, which we will call a ; and $\alpha - \beta$ is a variable angle, which we will call θ ; then, substituting and putting r for the variable radius, we have:—

$$r\theta = a,$$

and, clad in this classic garb, readers who have dwelt in the seventh heaven of mathematical bliss will recognise an old friend, the "reciprocal spiral." To show the nature of the complete curve, it is continued in the diagram at each end by broken lines, and towards the origin it approximates more and more to a circle with every revolution it makes, according to the law—

$$r_n = \frac{a}{n\pi}$$

where r_n is the radius at the n th crossing of the initial line, and by taking a and n of suitable dimensions we can get as near as we like to any sized circle. By making a very small, the whole curve approximates to the initial line; and if we take it small enough we have the special case of the radiating straight line. Thus, from this spiral we can get in our photograph a right line at any degree of obliquity; and perhaps enough has been said to make clear the general law.

The panoramic projection of a reciprocal spiral in a horizontal plane with the camera at its origin is a straight line, and only this curve or some special phase of it is so rendered.

Before leaving this there is just one other thing—the photographer would want to know the length of the portion of the curve he intended to use. From the equation we get the length of the part of the curve between θ and θ_1 , equals:—

$$s = a \int_{\theta}^{\theta_1} \frac{\theta_1}{\sqrt{\theta^2 + 1}} d\theta$$

and integrating we have:—

$$s = a \left(\frac{\sqrt{\theta^2 + 1}}{\theta} - \frac{\sqrt{\theta_1^2 + 1}}{\theta_1} + \log_e \frac{\theta_1 + \sqrt{\theta_1^2 + 1}}{\theta + \sqrt{\theta^2 + 1}} \right)$$

where θ_1 is the higher value of the angle, and, of course, is measured in circular measure from the initial line, where $\theta = 0$. Applying this to Fig. 2, where our unit of length is the foot and $a = 32\pi$, we find the length from B to B, a little over 157 ft.

But in all probability it would be as difficult to get a photographer to look at a formula of this kind as it would be to get Ludendorff to let you arrange his men; so perhaps a better way would be to plot the curve to several values of a , then step out the curves and the radii with the compasses into equal

lengths; and this would give a rapid approximate way of finding what one wants.

Before leaving this subject there are several practical points to consider. Where shall we put Ludendorff? In Fig. 1 it will be seen that the centre-line of the picture passes through the horse's head, and, therefore, he must be placed so that the mid-angular line—in this case the 90 deg. line—passes under the head of his charger. Another point to consider is what would happen if, instead of terminating the group at B and B', we continued it along towards the origin as far as the curve is

Fig. 3.

marked out in the diagram by the broken line, and also at the other end along the straight for half a mile or so; and then, starting the Cirkut camera at the beginning of the group, let it run round for two and a half revolutions? Still keeping to the 12-in. lens, we should want a 16-ft. film for this job; but to see the sort of thing we should get, draw a long rectangle to represent the picture (Fig. 4). The group will begin three times over and end three times, and if we draw a straight line from the bottom left-hand end of the rectangle to the horizon at the other end to show the line upon which the complete group is standing, the diagram will be completed by a line of 240 deg. and one of 180 deg. from the commencement of the picture and two lines of the same lengths at the end; and as these short

Fig. 4.

lines are necessarily repetitions of parts of the long one, all five will consequently be parallel to each other.

The practical outcome of all this is what every user of a panoramic camera knows: avoid such a position that gives a long, straight line, which in perspective ought to be parallel with the ground line; if we can get to something like 45 deg. from this position the curvature will, as a rule, be quite negligible; all radiating lines, and also parallels to these lines, if a fair distance from the camera, will be straight in the resulting panoram because, like the circle, they are special phases of our spiral.

A knowledge of the rigid conditions for a straight line will do the operator no harm, and even sometimes be helpful to the practical man.

When only a moderate angle is included in a panoramic view, it is not beyond the realms of feasibility to bring the picture into ordinary perspective by copying; the only conditions necessary being to bend the negative into the same curve that it had during exposure; and then project the image by means of a lens at the centre of the curve on to a flat surface normal to a line passing through the centre of

the curve and the middle of the negative. This is shown in Fig. 3, where we may suppose the negative was taken with a lens at 12 inches focus, and is therefore bent into a circular arc of 12 inches radius, and is being copied with a lens of 6 inches focus, which will give us a copy corrected as regards perspective, and of the same size as if the negative had been taken in the ordinary way with a 12-in. wide angle lens. Of course, the corrected copy will be longer than the panoramic view. In regard to the optical system, it is not at all necessary to have an anastigmat; some old-fashioned thing with a field as round as a football will do better; and perhaps a thin spectacle lens with a small stop right in contact with the glass best of all. Or, of course, the lens could be rotated during exposure; but then we should lose the advantage of roundness of field. Some years ago a lady took a picture of a castle in Scotland with an Al Vista camera, held so that the lens made a vertical sweep. The towers of the castle came out like barrels, but a correct bromide print was made in the way indicated above. A special optical system would have to be devised to cover anything more than a very moderate angle, and, in many cases, *true* perspective over a very wide angle would prove more objectionable than panoramic projection.

In the Cirkut camera we have great advantages: we can include any angle up to 360 degrees or more; we can focus; and we have usually three different foci to choose between; but, in the matter of range of time of exposure, it is the biggest sinner of all the panoramic cameras. The quickest

exposure is literally too slow for a funeral, and the longest possible time you can give is too short for a dull subject on a dull day. In cameras of the Al Vista and Panoram class, we could tackle ordinary hand-camera subjects on a bright day; and for a still subject on a dull day we could fix the camera on a steady stand and increase the exposure to anything we liked by swinging the lens to and fro as many times as necessary. And on some patterns of the Al Vista a brake, in the form of an air vane, was fitted, which not only increased the exposure, but also amused the group while it was being photographed.

In the matter of fitting new lenses to panoramic cameras this, in general, is impractical, except in the case of the Cirkut camera, where a new lens will mean also a new set of pinions, and the number of teeth to the pinions will be inversely as the foci of the lenses. There will be several points to attend to in making such a substitution, which are of more practical interest to the camera maker than the photographer.

In view of a recent patent for a camera in which the image is received on the inside of a cone ("B.J.," Dec. 27), it may be as well to define panoramic projection as used in the above article as the projection by straight lines from points on the object through the centre of a vertical cylinder on to the cylindrical surface itself; the intersection of these lines with this surface forming the image, which is afterwards viewed when the cylindrical surface is spread out flat to form the panoramic picture.

C. J. STOKES.

PRACTICUS IN THE STUDIO.

PRINTING PROCESSES FOR PORTRAITURE.

I FIND that nowadays people are rather apt to get into a groove over their printing methods and apparently forget that any other process exists except that which they happen to be working. It thus occurs to me that a brief review of the different printing media at present available, with notes on the characteristics of each, would be of service to those who wish to vary their work.

The uncertain character of daylight in Great Britain has made bromide and gaslight papers very popular, and an overwhelming proportion of portrait work is now produced upon them, but thanks to the almost universal supply of electric current, we are not now altogether dependent upon daylight for what may be generally classed as "printing out" as distinguished from developing processes.

The quality of the negative is an important factor in the production of the print, and only a small proportion of current negatives would yield even a passable result upon the old albumenised paper which for many years was almost exclusively used, so much so, in fact, that a print was hardly regarded as a "real" photograph unless it was made upon it. By reason of the quality of the negative required, and because it was impossible to produce it by modern factory methods albumenised paper is now only a memory, and it is impossible to procure even a small quantity through the ordinary channels. Hence it is unnecessary to touch upon it otherwise than by way of a reminiscence. Bromide paper in its various grades has taken its place, and I therefore put it first upon the list as being the process for the million, or that proportion of it who practise photography.

Although in such general use, few portraitists fully appreciate the wonderful variety of surfaces, speeds, and character of emulsions which are available. I cannot fairly allude to any specific makes by name, but will be content to refer my

readers to the advertisements in the B.J. Almanac, and the advertisement pages of the weekly Press. Bromide papers may roughly be divided into several groups, although these somewhat overlap each other. We may divide them by speed, that is to say, the time necessary to produce a print from a given negative by a given illumination; by the degree of contrast which can be obtained from the same negative by the surface texture, and by the colour of the paper base itself apart from the image. Thus we have "slow" and "rapid" papers, hard or contrasty, and soft, rough, smooth "platinum matt," "satin," and glossy, these giving a range from rough drawing paper to a surface like glass. In many cases certain grades come into two or more of these classes. Thus we may have rough rapid, smooth rapid, hard cream and soft cream, and the same in white. In this great variety lies one of the principal advantages of bromide paper, for there is hardly a negative which is capable of being printed at all for which a paper which will give the best result cannot be found. Many printers use only one variety of paper, and trust to their skill in exposure and development to produce even results from all classes of negatives, but from experience I can assert that a very ordinary worker can produce a better result upon "hard" paper from a flat negative than an expert can upon the average kind. Therefore I advise every printer to have by him a small stock of special papers, so that he can at once select the quality necessary for exceptional densities of image. While not recommending this course to be carried too far and to encumber oneself with too many kinds, I would point out the influence of colour and surface in certain cases. Suppose that we have a hard, chalky negative; we can use for this a "cream crayon soft" paper. This not only reduces the contrast of the image but tones down the glare of the whites, while the slightly rough texture gives further aid

in the same direction. With a very soft negative we may choose a satin surface paper, that is, one with a semi-gloss, which gives a richness to the shadows. A full gloss paper would be even better, but for high-class work a glossy surface is rarely acceptable. Further modification may be obtained by toning the image to a sepia colour, a course generally advisable with harsh contrasts, as brown and white usually gives a softer result than black and white when both prints are of the same quality. I strongly deprecate the practice of toning bromides irrespective of quality; every day thousands of prints which are of fairly good quality in black and white are spoiled by being converted into poor, flat, rusty sepias. If I have the slightest doubt as to the resulting tone of a print I would leave it in black and white, and if the order were for sepia prints I would ask permission to submit a black and white print when sending the proofs.

Gaslight papers closely resemble bromide in the points I have already mentioned, so that it is not necessary to deal with them at length. I should like, however, to say that besides the "contrasty" qualities which are most used, there are special kinds which, though very slow in action, will give splendid results from dense negatives. These papers require a very strong light for printing, several fifty-candle-power lamps being needed in the printing boxes.

Gelatino-chloride or P.O.P. was not so long ago almost universally used for portrait work, but is now little in favour, especially among the cheaper class of studios. A few good class firms still find that the warm tones so easily obtained upon it are acceptable to their patrons, and wisely adhere to it. Certain warm browns and reddish tints closely approach the delicacy of carbon, and will always be popular, but the purple black tones are now quite out of fashion. P.O.P. requires much greater care and cleanliness in working than bromide, which may account for the latter superceding it.

Self-toning papers, which are mostly collodio-chloride, possess many advantages, although they are the slowest of the printing out sort. This defect may be largely overcome by employing an enclosed arc for printing, when the time is much shortened. A great range of tones from warm sepia to a blue-grey may be obtained by variation of the strength of the hypo bath and for the greys a preliminary soaking in a solution of common salt. Matt and glossy surfaces and white and cream bases are available in this class of papers. A variation of tone may be obtained by using a platinum toning bath as employed in the double toning of ordinary collodio-chloride paper. I have used much of this paper, and find that the prints stand very well. Some, which are fifteen or sixteen years old, seem quite fresh. Self-toning gelatino-chloride is also made, but I have not found so good a range of colours with them as with the collodion. Moreover, they cannot be dried by heat, as the latter can. Some few photographers have used what is

termed salted paper for large work. This has to be prepared at home by coating drawing paper with a solution of chloride of ammonium or even common salt, and floating upon a bath of nitrate of silver. The prints may be fixed without toning, or they may be toned in any of the gold baths used for P.O.P. Strong negatives are required, as the image is inclined to be rather dull as compared with that on an emulsion paper. The surface is very agreeable, and with suitable subjects the results are highly artistic.

Platinum printing like carbon stands in a category of its own, and occupies the first place with those photographers who put quality before cost. It is, next to ferro-prussiate, the simplest of all printing processes, and is not only pleasing but permanent; it is actually a "thing of beauty and a joy for ever." Platinum papers can be obtained in rough and smooth surfaces, and on white and cream bases. As there is no practically useful method of toning, special papers and solutions are prepared for black and sepia prints respectively. One important quality of platinum prints is their absolute flatness when finished; as there is no coating either of gelatine or collodion there is no risk of curling, and if attached by one edge to a mount they will lie close to it no matter what the condition of the atmosphere may be. It should be clearly understood that the word "platinum," when applied to bromide paper, refers to nothing but the appearance of the surface. There is no platinum in the coating, and the image is no more permanent than that on ordinary bromide papers.

Carbon printing is unique as regards the great variety of colour and surface in which prints may be produced. Although in portraiture only two or three are commonly used, such as sepia, red chalk, and warm black, at least fifty varieties of colour, including reds, blues, greens, browns, greys, and many others, and a score of different weights and surfaces in the transfer papers are regularly supplied. So that it is possible to make carbon prints which closely resemble those by any other photographic process; and, needless to say, all are absolutely permanent. It is worth noting that, in spite of war restrictions, the price of carbon materials has shown but little increase in price. Many are deterred from attempting carbon printing by the idea that it is very difficult, but this is not the case if ready sensitised tissue be used, and if the work be carried out systematically it is little more troublesome than P.O.P., and the extra price obtainable will amply justify the additional work.

I have carefully abstained from giving working details of any process, as this has been done over and over again, but in case of any difficulty, any desired information will be given through the usual "Answers to Correspondents" column. My object has been to point out what materials photographers have to hand for the production of such prints as may be needed for any class of business.

PRACTICUS.

HOME PORTRAITURE.

[In the lecture given before the Royal Photographic Society some months ago Mr Foster Brigham gave from his wide experience many pieces of advice on the practice of portrait photography in the sitters' homes. Some of his hints were reported in our columns at the time, but we now avail ourselves of the opportunity of adding others to them by reprinting the official report of his lecture, which appears in the current issue of the Society's "Journal."]

No special apparatus was required: anything capable of making a negative could be used. Most of the portraits to be shown were made with a Goerz-Anschutz hand-camera, a particularly awkward instrument for the work, owing to the lack of a swing-back, a very necessary adjustment when there were perpendicular lines such as of panelling in the background.

The usual reason given for not indulging in portraiture was the absence of a studio. He had worked in various studios for fifteen years, and had found that there was something very conventional

about a studio; one got a result which looked artificial, and artificiality was the antithesis of art. Photography was at its best when naturalistic. Most of the portraits he was showing that evening were taken in a room measuring twelve feet by ten feet and containing one window. It was said that the light should come only from one source, but he had found two or more windows a very great help. Some of the examples were taken in a transformed aeroplane packing-case with three small windows put into it. When going into other people's rooms for the purpose of taking portraits

it would be found that each room presented a fresh problem and a refreshing view point.

One of the elementary rules of portraiture usually taught was that the background should be quite plain. This was a good, safe plan, but difficulties were not got over by going round them. Hanging committees and critics were apt to let rules of this sort run away with them. The young photographer was told, quite rightly, that he should not take a group in the sunlight, but if he were never to get beyond that he would not go very far. In the same way, in home portraiture, which might be regarded as any sort of portrait which was not taken in a studio, the background must be studied with some idea of going beyond the elementary. The background selected by the photographer showed fairly clearly the stage of development at which he had arrived. The first stage was that in which he placed the sitter against anything which happened to be handy, often an ornate wall-paper. In the second stage he used a painted conservatory or seashore background; and the third stage was that in which his background was quite plain. This last was now so much used that it had become a convention. The fourth stage was represented by a background worked-in in such a way as would assist the composition. Strong high lights as accents were daring, but if used with discretion in the right place they were effective. He showed illustrations of various kinds of backgrounds, and reminded the meeting that the old portrait-painters introduced something into the background to indicate the sitter's profession or calling. A self-coloured wall, panelling, or curtains, especially if escaped to help the composition, or any real solid object free from distracting high lights or fierce contrasts, made the most natural pictures, and might be termed the fifth stage.

When the sitter was a personal friend one had something to say about his or her clothes. What was required was, in the case of a lady, simple clothes with flowing lines—not an easy matter with the present fashions! With regard to posing, it was true and rather true to say that the best way to pose was not to pose. One tried to catch the characteristic deportment and expression that enabled a person to be identified a hundred yards away. It was very difficult to avoid the camera-conscious look, and a good way to do so was to let the sitter to perform some simple action. The question of pose

was intimately related to that of composition, which might be defined as filling a space in a manner pleasing to the eye. There should be nothing in the picture which gave the suggestion of any part of it being insufficiently supported. Stability was of the very essence of composition: one of the most suitable general forms one could have, and one very easy to get with head and shoulder portraits, was that of the pyramid. The old painters were fond of combining the pyramid with the S line, as, for instance, Rubens' "Madonna and Child," and the well-known "Madame le Brunn and her daughter," the composition of both being almost identical.

As soon as one got away from the pyramid or the diagonal form it was necessary to have holding-in lines—that is, other suggestions of support which would keep the picture fixed in its space. Judicious trimming would often supply these lines when the background did not provide them.

It was a difficult problem to fill an oval satisfactorily. One way was to have some lines in the picture which themselves partially conformed to the oval or a very bold head and shoulder portrait of pyramidal form could occasionally be trimmed in this way. As far as possible the light of the room in which the sitting took place should be used just as it was normally, without any window darkening. The longer he practised photography the more he felt that any lighting was good lighting so long as one got the tone values right. Many books had been written on the subject of lighting. Inglis, an American, who wrote one, said that the only system of lighting was his—i.e., the light coming from a small square at an angle of 45 degrees from the side and front of the sitter. Another writer advocated the division of the room and light into a certain number of squares, and when a certain effect was produced and noted, that effect could be repeated at will. That was ridiculous, as the interior lighting varied with every change outside.

The photographer must school himself to see and appreciate lighting effects. If the play of the light and shade on the sitter's face could be properly appreciated, good lighting could be found anywhere.

In conclusion, he said that a portrait would not be satisfactory unless it indicated something of the character of the sitter, and it was very difficult to catch and record just that expression.

PROGRESS OF PICTORIAL PHOTOGRAPHY.

[A booklet of which we have recently been the recipients contains an interesting review of the present tendencies in pictorial photography in the shape of an interview with Mr. Clarence H. White, one of the prominent exponents of art through the medium of the camera in the United States, and the director of a school of photography founded for the purpose of providing systematic instruction in this branch of work. It is not so many years ago that Mr. White appeared before the British photographic public as one of the young men enthusiastic in establishing altogether new ideals and new forms in pictorial photography. The American school, as it was then styled, came in for a large measure of derision, but it has been easy to trace its influence in the exhibitions of pictorial work during the past ten or fifteen years. Equally there has been observed some abandonment of the more extreme features which characterise the early work of these American pioneers; and therefore it is interesting to have Mr. White's conspectus of a stage of progress in which he has taken a notable share.—EDS. "B.J."]

"Mr. White, I want to ask you whether you think that pictorial photography has made substantial, or any, progress in America during the past year?"

"I believe that pictorial photography is progressing, but its progress is not to be expressed in terms of a year. Pictorial photography is expressed more or less in terms of epochs. My observation is that there has been a big growth in—well, I cannot say exactly in a year, but in the last four or five years. I may say that this growth is evident even in places remote and in places where we once heard practically nothing of pictorial photography, but find now large groups of very active and earnest workers, most of them producing very high-class work."

"What has been the influence of the pictorial photographers of America on photography during the past year?"

"The influence has been one of substantial encouragement. For one thing, we have sent to various museums important exhibitions of photographs. Here is a little incident that came to me a few days ago that might help to answer your question. A young

woman, a member of our organisation, was in the Cleveland Art Museum. While she was in the room where our photographs were being shown she saw the director approach with an English artist, and she overheard this conversation. As he passed the door the director asked the artist to go in with him and see the exhibition of photographs. The artist protested that he did not care to go in and that he did not believe in it, and that he did not think there was anything in pictorial photography. The director quietly insisted on his going in, saying that he felt very decidedly that there was more real enthusiasm manifested in this exhibition of photographs than there was in a group of etchings that was shown in another room. This is significant of a change of attitude toward photography as an art, and there are about sixteen different museums in which this state of things is being revealed. I have in mind the Newark Museum. They had a collection of these photographs displayed in a most beautiful way in the Newark Public Library, and along with it they showed copies of all known magazines devoted to the subject, with portfolios representing examples of the work

of photographers in Europe, and a person who came to view these pictures could then turn to these magazines or portfolios and study them."

"What effect would you say war conditions have had on pictorial photography?"

"In America the effect on pictorial photography has been, I would say, rather to dampen enthusiasm or to discourage it. There has been a feeling that all activities should be directly connected with the war, and that photography should share in this; that pictorial photography should be devoted to placarding the war or the spirit of the war, a sort of war propaganda, rather than purely pictorial work. Abroad, one of the interesting things I have noticed in connection with the catalogue of the Royal Photographic Society exhibition, the oldest photographic organisation in the world and the most important one, is that the exhibition reveals very little of war-time activities. They are showing pictorial photographs, technical photographs, Autochromes, and every branch of photography. The pictorial section had no particular bearing on the war, nor had the Autochrome nor the scientific section. The section of forty-nine prints loaned by members of the British Military Service formed the only contribution directly pertaining to the war. In the advertisements in this catalogue there was practically no reference to the war, and an advertisement of a photographic school in connection with the Regent Street Polytechnic contained no mention of a war course, but did mention conspicuously their pictorial work."

"Has any development along the lines of what we might call cubistic art got into pictorial photography?"

"Yes, it has gotten into photography to a slight extent, but I am loth to call it cubism or any similarism. The development of modern art, I think, is in the direction of construction; and construction—picture construction—applies to photography as definitely as it applies to painting and other art. Indeed, a great feeling of the need of this has expressed itself in connection with photography."

"What do you mean by the 'construction' of a picture? Anything different from the rules of composition as usually understood by artists?"

"The rules of composition as usually understood have been too narrow. We might say there are no rules, but there are certain fundamentals. These fundamentals have been made to apply in a great variety of ways. Take this print, for instance. (Mr. White took up a photograph showing some peculiar architectural effects.) Here is a little of what we might call cubism in modern photography. We first look at it, and we get pleasure from the play of light and dark on the object. It produces a sense of satisfaction to the eye, and yet when we examine it more closely we feel that the artist has violated the rules of what might be called composition. We must construct our rules of composition from examples rather than make the construction that is demanded by our art out of formal rules."

"Can commercial or professional photography assimilate pictorial principles?"

"I believe commercial or professional photography should be pictorial. Pictorial photography is simply a name applied to photography that really has, or should have, construction and expression."

"Has colour photography a future? Has the Autochrome a future?"

"I feel that the Autochrome has already demonstrated its position, and the colour print will eventually take a definite position. Processes will be simplified in such a way that it can be used more successfully by the amateur, and the amateur's work and enthusiasm are necessary to its development."

"Has platinum paper been in the market during the past year?"

"Black platinum paper practically disappeared from the market, but sepia platinum paper has been obtainable."

"What is the best substitute for platinum paper?"

"THE BRITISH JOURNAL OF PHOTOGRAPHY, a recognised technical publication devoted to photography, has said that printing *de luxe* should be done on platinum or palladium, which are absolutely permanent papers. Carbon is also to be classed with these as permanent papers. There is no real substitute for these papers, and I trust that they will eventually be again available."

"What do you think of the bromide papers made on Japan tissue?"

"I think they have produced very beautiful results."

"Is bromide paper the best available paper of the future for pictorial effects?"

"Bromide prints are most beautiful, and the quality of some bromide prints that we see is such that it is difficult to distinguish them from platinum, which is surely the greatest compliment we can pay them."

"Can the bromoil process ever be used except by expert workers with a gift of patience?"

"I find that the bromoil process is often used by people who are not experts, but amateurs with a desire to achieve a good photographic result. To be an expert, of course, would help very materially in producing this result. There are very few expert bromoil printers."

"Has the 'gum print' passed? If so, what has taken its place as a medium of expression for workers who think they have something to express that is beyond straight photography?"

"I think the 'gum print' has not passed and is not likely to, but to become really of greater interest as time goes on."

"Are as many 'gum prints' seen in exhibitions now as formerly?"

"No. The reason, I think, is that some of the best workers in the medium are not interested particularly in showing their work in exhibitions."

Mr. White here turned to some choice gum prints that were hanging on the walls and pointed out their good points.

"Is carbon paper now used to any extent?"

"Carbon paper is still available, and is still used, but not so much by the commercial photographers, and probably a little less by the pictorialists, because of the introduction of new processes like oil and bromoil; but many workers have continued to use, and still use it, with admirable results."

"Has 'home photography' had any growth in popularity during the year?"

"Probably the greatest development of photography is in home photography or home portraiture. During the last five or six years practically every professional studio has been obliged to introduce home portraiture."

"Have there been any notable inventions in photography during the year?"

"I want to make a confession—the inventions in photography are not of so much interest to me as the development of the inventions that are still to be perfected."

"Has the so-called 'fuzzy school' made any converts during the year, or is the tendency to go back to sharp, or sharper, prints?"

"I do not think there is a tendency to go back to sharp or sharper prints, but there has been, or there is getting to be, a better understanding of the soft focus lens."

"Has the pictorial school of photography had any influence on what may be called the chief field of photography, in its larger aspects, at present—the moving-picture drama?"

"I feel that probably there pictorial photography has its greatest influence. We find very few serious film producers who do not study very carefully the construction of their pictures and the lighting of them, together with the proper motion-picture appeal—the appeal of the acting. They are really looking for all expressions of light and varieties of focus that the pictorial photographer has been interested in."

"It is said that D. O. Hill, the Scotch artist, who for a while practised photography with genuinely pictorial results, used paper negatives. Was his success due in any measure to this fact?"

"I don't think it handicapped him, and in many instances I feel that it contributed to the simplification of his portraits."

"Do you recommend the use of colour filters in pictorial work?"

"I do."

"Do you recommend fast or slow plates for pictorial work? What about films?"

"I would prefer to use, whenever possible, a slow plate. Films eventually, I believe, will be the only thing used, though not necessarily film packs or roll films."

"Do you mean that the glass plate will be discarded and cut

must be used? Is it not the fact that most practical photographers find a great advantage in using glass plates?"

"Of course, the advantage of the glass plate is that it is easier to handle; but a good thick celluloid film is almost as easy to handle, and those films are easily filed. They are not breakable and they are being made now in all the various emulsions. Their great advantage is in their lack of weight and their non-halation qualities. A great many photographers are burdened with plates and the filing and storing of them become a big problem."

"Have any improvements in cameras been made during the year?"

"As I see it, cameras have been improved in the direction of the needs of the pictorial photographer in that they have longer bellows extension and larger front-boards and are constructed for stability. As the photographer is working more and more in the open, this is necessary."

"What kind of a camera do you recommend for pictorial work?"

"Personally I feel that every photographer should first learn to photograph with a view camera. As his work develops he finds that it is a matter of getting his inspiration from incidents of life rather than building up his compositions in front of a view camera. Here is where the reflex camera is a great help."

"Then you recommend the reflex type of camera for serious pictorial work?"

"Yes, I do."

"Would you fit this type of camera with a soft-focus lens?"

"Yes, and also with an anastigmat."

"Have any new lenses been put on the market in 1918?"

"None that I know of."

"What do you think of the use of the soft-focus lens generally in pictorial work?"

"I think if pictorial photography were suddenly robbed of the soft-focus lens it would be a catastrophe."

"Can the same results be secured with the anastigmatic lens by throwing it slightly out of focus?"

"No, for the results obtained with the soft-focus lens are due to its construction."

"What size camera do you recommend for pictorial work?"

"I think the tendency of the pictorial worker has been to use too large a view camera. It has been demonstrated that size does not determine the artistic value of a picture. I would recommend a camera that is not a burden to the person using it."

"Do you recommend workers to make enlargements from a small-sized negative for exhibition purposes? and, if so, what size enlargement do you prefer?"

"I should feel that the work above 11 x 14 is a mistake generally, and that a picture can be just as beautiful and in the long run more beautiful when it is kept within the dimensions of the 'whole plate'—6½ x 8½ ins."

"Do you recommend the working up of negatives for pictorial effect?"

"My preference is for photographs that have not been worked up, but if a man is successful in doing this to the extent of losing sight of the manipulation in the completed picture I see no reason why it should not be done, and I think it has been done with success by some good workers."

"Do you object generally, to manipulation or 'dodging' of prints or negatives as tending to produce hybrid results?"

"I feel that the practice of doctoring negatives is a bad one, but to achieve a result, if it is well done, it may be justifiable."

"What is the most approved fashion of mounting prints this year?"

"The most approved fashion is the one that was established many years ago in the presentation of etchings and engravings—a white or slightly toned mat, sometimes with a 'countersunk centre.'"

"Do you think that an ambitious amateur who desires to do good work can best improve his methods by studying exhibitions, or by studying books on art and composition?"

"I should say that the books on art and composition are of little value without the exhibitions, and that if worked together the book is made more valuable by the exhibition and the exhibition more valuable by the book, but the combination is absolutely necessary to achieve results. The tendency very often is that a continued

study of books or exhibitions rather satisfies the worker, and he does not devote himself to his own problems of creative work."

"What is the greatest weakness in the work of the young photographer, and how can he best overcome it?"

"I think the greatest weakness of the young worker is the lack of something to express. He is too much interested in the photograph for the sake of the photograph alone—that is, in the medium or in the taking of the photograph itself. The photograph should express something."

"Just what do you mean, Mr. White, by 'expressing something'?"

"You get down to a very important point. The expression in a photograph may come from what we might call the design of the photograph or the distribution of light and dark to produce a visual sensation, just as a fine rug or piece of lace gives us a satisfaction in design, an expression in design. We can also introduce that into the making of a portrait, and embody not only a representation of the person's features, but create at the same time an interesting design or a better distribution of the parts of a portrait to make it convincing and definite."

"Do you mean that an amateur should go out into the fields with a preconceived idea of finding something to express, of making a pattern or doing something 'original'?"

"He should go out into the fields with an open eye and open mind to be moved to an expression of his appreciation of pattern, his appreciation of tone, of values, etc. Let him leave the mind open, and that will tell him what to express. He gets his inspiration from Nature, and he contributes to Nature just so much as he has of knowledge of photography, knowledge of composition, knowledge of tone values—he expresses himself that way. I do not believe he should go with a preconceived idea of what he is going to get. He should be moved by his subject. If he is not, he will become blind to the most beautiful aspects of Nature. That is the interesting thing of Nature; the changing light and shadow are never twice the same. The light is continually changing, and he has combinations and variations that a man with a preconceived idea will miss, and in photography that is the most impressive thing—that it can record those subtleties."

"Do you recommend workers to send only new photographs to the exhibitions? In other words, should a worker try to get new subjects continually, or send his older, and perhaps better, work in more limited amount?"

"It would be better to send his older work and keep the new photographs at home until he has studied them carefully."

"Do you regard photography as giving fair scope to the art impulse in people who have that impulse but are unable to devote their time to painting, etching, or other graphic art?"

"The question really expresses the idea that photography is supposed to be taken up when they cannot do the other thing, which I feel is a mistake. Photography is an expression, not necessarily as important or vital as the others, but it is an expression, and it can be used along with the others as well as alone."

"In other words, you feel that photography stands on its own merits?"

"I feel that it stands on its own merits absolutely."

"What, in your opinion, is the distinction between an amateur and a professional photographer?"

"I think the distinction between the amateur and professional photographer is difficult to draw. The greatest distinction that I can see is when the word amateur is applied so that it reveals the love of the amateur for his work rather than the sense of the duties involved in it. That is what the amateur gets out of the work; the professional's aim is too often what he can get out of it in the sale of his products."

"Can the pictorial photographer make a living in America under present conditions, or is the photographer who wishes to make a fair income to be recommended to confine himself to so-called 'commercial' or 'professional' work?"

"Being a pictorial photographer does not necessarily prevent his making a living. The pictorial photographer, if he is a good one, is naturally concerned more in producing a result than in marketing the result; and as a consequence sometimes he suffers. The pictorial photographer in reality ought to be a financial success, for the

tendency is strongly toward the development of the work in that direction."

"Will the ending of the war have a favourable effect on the future of pictorial photography and on the pictorial photographers of America?"

"I should say very decidedly yes. It will naturally liberate a great many repressed spirits, and that very liberation will express itself by bringing the worker in closer touch with nature, and the results will show this. I feel that the development after the war is going to be in the direction of art expression. As a specific instance, my own son, who was sick and tired of photography in general, has manifested a greater interest in it since he has been in the Army in France, through coming in contact with the old chateaux and the interesting art treasures that he has seen. He has developed a greater respect not only for art, but for photography; and this single instance has doubtless been repeated in thousands of cases on the part of our soldiers in France."

AMIDOL v. M.Q. FOR BROMIDES.

(From Rajar "Trade Notes.")

We have heard many discussions amongst professional photographers as to whether amidol or M.Q. is the most suitable for bromides, and there appears to be considerable divergence of opinion. Our papers are suitable to both, and, whilst many workers are producing perfect results with amidol, we are inclined to think that, from a commercial point of view, the M.Q. developer is to be preferred. The quality of blacks produced by either is equally good, and the tones in the sulphide or hypo alum baths differ very slightly.

With amidol, a great deal depends upon the skill and care of the worker in daily compounding the developer accurately, whereas the M.Q. can be made up in large quantities of constant strength and stored for convenient use—a point that will be appreciated by those who run more than one studio. The disadvantages of using amidol are, for brevity's sake, tabulated below, and in common fairness we will admit that most of these can be met by the careful personal attention of the skilled man.

1. Temptation to guess the proportions of amidol, sulphite, potass bromide, and water.
2. Bad keeping qualities of the mixed bath, and the daily risk of particles of dry amidol settling on drying prints or negatives.
3. Great susceptibility to the action of potass bromide; consequently when large batches are developed, the liberation of bromide from the paper introduces an element of uncertainty.
4. Rapid contamination of the fixing bath, unless the prints are washed after development, and risk of staining the gelatine or paper base.
5. Quick staining of the fingers and finger-nails.

With M.Q., the making up of the developer can be a once a week job, by a principal if possible, making the solution double strength and storing it in 80-oz. (Winchester) bottles. There is no daily weighing out or measuring, as the developer only needs mixing with an equal part of water when required for use. The strength is constant, and the prints can be developed by time, a method that produces the most perfect results. The fixing-bath does not become quickly discoloured, nor do the finger-nails stain badly.

The formula for M.Q., recommended for use with our papers and cards, is:—

M.Q. DEVELOPER—DOUBLE STRENGTH.

Monomet	1 oz.
Hydroquinone	4 ozs.
Sulphite of soda (crystals)	2 lbs.
Carbonate of soda	2 lbs.
Potass bromide	1½ ozs.
Water (to make 8 Winchester)	4 gallons.

Obtain a three-gallon jar three-quarters full of hot water, add the monomet first, stirring until dissolved, then add the hydroquinone, sulphite, and bromide, stirring until all is dissolved. Add the carbonate last. Have eight clean Winchester at hand, and with a measure or bottle fill them to equal height with developer. Then add water to fill the bottles and stopper them.

SHOWING LARGE PROOFS.

(A Note in "Camera Craft.")

THERE is a certain professional that I call upon who has worked out, with the aid of his receptionist, a plan that seems to give the most gratifying results. When the customer first calls the latter makes no special effort to sell large sizes, further than to show them and quote prices only, as a matter of showing what is available; in fact, if there seems to be any doubt in the customer's mind the receptionist kindly advises that a small or medium size be considered, because it is quite easy to make enlargements from the small negatives if a larger size be ultimately decided upon. The customer takes very kindly to this somewhat radical change from the overdone urge of large sizes and high-priced work, and the frame of mind so established is a much more desirable one and one more conducive to future good business than the antagonistic one created by even the slightest suspicion of what too often passes as "good salesmanship." The sittings are made, but here is where the plot deepens: instead of making the small negatives, the operator exposes the 6½ by 8½ plate the studio uses for all its work. When the proofs are shown all have been made the small size by using the enlarging and reducing camera, while the one or two best ones that the photographer desires orders from are made full size. Any receptionist or proprietor of any experience can readily see how much easier it is at this time to let the customer order the large size, and from the desired negative, particularly if the pictures meet with his approval, than it is to try and force an order for large sizes before the pictures have been made. The imaginary "enlargements" are of unexpected good quality; they suggest that even still further enlargements will be pleasing, and that makes it easier than would otherwise be the case to get an order for an extra size enlargement or two. Of course, there is an element of deception introduced, but it is one that benefits the customer, even if the smaller size is really all that is wanted, for the reason that the reductions from the large negatives are as good, if not better, than would be the same size of contact prints, and the contact prints from the large negatives are better than enlargements would be, and, of course, just as good as if ordered in the large size at first. All the deception really does is to give the customer an opportunity of changing his original order for small work to larger without suffering the penalty of not having so decided at first. It, of course, involves a greater plate expense on the part of the photographer, but, as our professional friend advises, the extra cost is well worth the better feeling engendered, to say nothing of the larger orders the plan seems to automatically produce.—THE DEMONSTRATOR.

Exhibitions.

COLOURED PRINTS AT HAMPSHIRE HOUSE.

A most interesting series of coloured prints by Mr. and Mrs. W. Giles is now to be seen at Hampshire House Photographic Society, Hog Lane, Hammersmith, W. There are about thirty pictures shown, and they are throughout sketches, drawing, cutting the blocks, pigmentation and hand printing, the work of the artists' own hands. They owe their conception to the influence of the work of the artist craftsmen of Japan, but they are largely individualistic also.

Printing in colours from wood or metal blocks has its limitations, and the very narrowing of the field, as in Japan, had the effect of so focussing the artists' efforts as to produce results that within their own sphere are truly excellent.

In ancient Egypt the keynote of their sculptural monuments was a crystallisation of characteristics, and an elimination of details and non-essentials of form. This came about through two principal causes. The ideographic character of their writings, which persisting through thousands of years forced and fostered the endeavours of the scribes to attain simplicity; and the second cause was the refractory nature of the materials—granite and porphyry—they used. Precisely the same causes operating in Japan produced similar results. The Japanese learned to portray the utmost likeness and liveliness of the subject in the fewest possible number of strokes and colour.

Mr. and Mrs. Giles' works show the same feeling, but they also

have a more varied palette, and a more transparent and brilliant pigmentation. The exigencies of space preclude us from detailed descriptions. There is a lure about the works of these two stylists that is very attractive. One lingers and boiters in front of the pictures absorbing and observing; the eyes are gladdened and the soul is satisfied.

The Exhibition remains open (free) until March 6, every day from 10 a.m. until 1 p.m., and from 2 p.m. until about 7 p.m., on Thursday the whole evening also.

New Apparatus, &c.

The F. and S. Identification Outfit. Made by Kodak, Limited Kingsway, London, W.C.2.

We were recently interested in examining in practical use a piece of apparatus of which very wide use has already been made in the United States in connection with the prosecution of the war. Briefly, the apparatus consists of a self-contained camera and arti-

ficial light, serving to produce in rapid succession upon a band of film small portrait negatives under absolutely uniform condition. The negatives measure about $1\frac{1}{2}$ by $1\frac{1}{4}$ inches, and include on each one a record of the height of the person photographed, together with a registration number. The illuminating system is composed of a battery of half-watt lamps placed behind diffusing screens, and

affording an extremely even, but powerful, illumination. Thus, exposure is made by shutter in a fraction of a second, and the whole operation of taking the portrait need occupy barely more than a minute, inasmuch as the subject has simply to stand behind a framework attached to a horizontal platform, which also carries a camera. The height of this platform has simply to be adjusted to bring the subject's face centrally within the space of the frame in order for the exposure to be made. The sensitive film is wound from one spool box to another, as in a cinematograph camera, and may be bought in lengths for 150, 250, or 500 exposures.

The applications for such an apparatus as this are obviously very wide when it is considered that the instrument takes up floor space of only about 8 by 4 feet, and can be used wherever there is an electric circuit available. The making of portraits of season-ticket holders for attaching to the ticket is a question which has been discussed now and again. The F. and S. identification outfit would permit of the scheme being easily carried out in any railway office. Inasmuch as one may foresee a stricter regulation of the individual in this country, it can be well imagined that a portrait will form part of other licence documents, such as those used for driving a motor-car, shooting, admission to libraries, and the like. And it is certainly to be expected that any scheme of registration of aliens will embody such a feature, and will thus render it more efficient in controlling the movements of suspect persons.

The apparatus is made with the excellence of workmanship and regard to utility which characterise the manufactures of the Kodak Company, and is priced at £85, subject to a considerable discount.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, FEBRUARY 17.

- Bradford Photographic Society. "Colour Photography." J. W. Dawson.
Dewsbury Photographic Society. "Intensification and Reduction." W. E. Gondill.
South London Photographic Society. "Portraiture." W. Foster Brigham.

TUESDAY, FEBRUARY 18.

- Royal Photographic Society. "A New Process of Printing on Paper in Natural Colours." S. H. Williams.
North Wilts Field and Camera Club. Demonstration: "Bromide Printing." S. S. Hallett.
Hackney Photographic Society. "The Domestic Fly." Dr. G. H. Rodman.
Chelsea Photographic Society. Dark Room.
Manchester Amateur Photographic Society. Monthly Exhibition arranged by A. W. Burgess.
Birmingham Photographic Art Club. Copying by Artificial Light." W. F. Carter.

WEDNESDAY, FEBRUARY 19.

- Croydon Camera Club. An Evening with T. H. B. Scott, accompanied by some of his pictures.
Dennistoun Amateur Photographic Association. "Pictorial Work" (Illustrated). R. Park.

THURSDAY, FEBRUARY 20.

- Liverpool Amateur Photographic Association. "From Alp to Apennine." J. D. Johnston.
Brighthouse Photographic Society. "Walks in Lakeland." S. Greenwood.
Huddersfield Naturalist and Photographic Society. "Liquid Air." Dr. J. Bruce, B.Sc., F.I.C.
Hammersmith (Hampshire House) Photographic Society. "Enlarged Negatives." R. K. Lawton.
Hull Photographic Society. Y.P.U. Slides. Secretary.
Rodley and District Photographic Society. Monthly Competition: "Firelight."
Wimbledon Camera Club. "Romance of London." C. M. Forbes. Monthly Print Competition.
Tunbridge Wells Amateur Photographic Association. "Mounting the Print." G. C. Weston.

ROYAL PHOTOGRAPHIC SOCIETY.

The annual general meeting was held on Tuesday evening last, February 11, the President, Dr. C. Atkin Swan, in the chair.

The report of the Council was taken as read and immediately by some perverse motive read paragraph by paragraph. The society has fifty more members than a year ago, its real membership being 971. In financial affairs it has just paid its way with the aid of a surplus from the special exhibition fund raised in 1917 by its then president, Mr. John H. Gear. On the proposition of the President, seconded by Dr. Rodman, the report was adopted.

The Treasurer, Mr. A. H. Lisett, in making his comments upon the statement of accounts followed his accustomed course of

computing the cost of per member of such items in the expenditure as lighting, the JOURNAL, and salaries. The adoption of the balance-sheet was seconded by Mr. W. B. Ferguson and carried.

On the proposition of Mr. E. Smith, seconded by Mr. G. Hawkings, a vote of thanks to the President, council and officers was passed by acclamation.

The report of the scrutineers of the ballot was then read showing that voting papers to the number of 172 were sent in, and the following were the officers elected for the present year:—

President:—Dr. C. Atkin Swan, M.B.

Vice-Presidents:—F. F. Renwick and Dr. G. H. Rodman.

Honorary Treasurer:—A. Herbert Lisett.

Ordinary Members of the Council:—

F. C. Boyes,	F. Martin Duncan,
A. J. Bull,	E. W. Mellor,
Captain D. Cameron-Swan,	Lt.-Col. J. T. C. Moore-Brabazon
G. Bellamy Clifton,	Chas. F. Oakden,
H. Easenhigh Corke,	E. Sanger-Shepherd,
W. B. Ferguson, K.C.,	W. F. Slater,
Captain F. H. Grenfell,	W. L. F. Wastell,
J. Dudley Johnston,	J. C. Warburg,
Ernest Marriage,	S. H. Wratten.

The only other business of interest which followed was some discussion of the Society's attitude towards unnaturalised members and fellows of enemy nationality, whose names have been removed from the Society's lists. It was understood that it is the Council's firm determination not to restore them.

CROYDON CAMERA CLUB

Mr. F. R. D. Onslow gave a lantern-lecture on "Some British Birds and their Homes," being a repetition of that recently delivered at the Royal Colonial Institute, which led to some controversy in the Press. A most interesting subject was handled in a thoroughly happy manner, and the slides illustrated first-rate craftsmanship in every particular. Really wonderful considering the difficulty of the work.

Particularly ingenious were the methods by which shy birds were photographed in their habitat. Sometimes the lecturer camouflaged himself and camera as a rubbish heap. On the borders of Scotland a sham and hollow "scratching post" (God Bless the Duke of Argyll!) was used to contain the camera, operated from a distance by electrical or other release.

But the finest touch was when, with the assistance of a wig maker for the head, he assumed the guise of a sheep, a plan which was found most effective for stalking the game. Naturally, as he had to crawl on all fours, and over stony or marshy ground, he must needs be a bit of an enthusiast. The rig-up was first tried on a real sheep—one, by the way, possessed of formidable horns. It watched the gradual approach of the new breed with evident disfavour, but with no apparent suspicion, but when close quarters were reached it suddenly resolved to give the mysterious stranger a sharp lesson, and went for him all out. In self-defence Mr. Onslow immediately shot up to an erect position, and that sheep experienced the shock of a lifetime and bolted for all it was worth. Judging from a slide shown, even a highly intelligent sheep would be deceived, so natural was the presentation. Certainly, the expression seemed a trifle rigid; but then sheep are hardly famed for mobile countenances.

It was noticed that during the evening the Secretary, Mr. Sellors, at irregular intervals, and without apparent cause, chortled in joyful manner, and a question elicited the reason for this eccentricity. Both he and the lecturer employ exclusively "ordinary" brands of plates, and it happened that many slides included white birds against a blue sky, and rendered the feathers in beautifully graduated light tones against a grey background. Hence the Sellorian delight.

Probably most readers at some time or another in their lives have studied the pretty little birds which congregate on the esplanade or pier at the seaside, but these are a particular species, though the plumage widely varies, and a word of caution may not be out of place against climbing a tree to inspect the nest of a heron. The young birds have an objectional habit of being violently sick when disturbed, and in one case mentioned by Mr. Onslow a disgorged mixture of decomposed worms and fish unexpectedly applied as an

eye ointment to the climber nearly resulted in a nasty accident. A most hearty vote of thanks was accorded for an altogether excellent lecture.

HEREFORDSHIRE PHOTOGRAPHIC SOCIETY.—The general meeting of the Herefordshire Photographic Society was held at the Society's Rooms, 76, Eign Street, Hereford, on February 4. Mr. Ernest G. Davies presided, and there were also present Miss McAdam, Mr. A. C. Slatter, Mr. A. Naylor, Mr. W. Williams, Mr. W. A. Grosvenor, Mr. Gransmore, Mr. Brumbill, and Mr. A. Lovesey (hon. secretary and treasurer). It was stated that there were about fifty members, and the accounts showed that the society was in a sound financial position, a deficit of over £6 last year having been practically wiped out. Mr. Alfred Watkins was unanimously re-elected president, and thanked for his past valuable services; and the vice-presidents were Mr. John Parker, Mr. W. J. Humfrys, Mr. J. S. Arkwright, Mr. W. C. Gothen, Mr. E. G. Davies, Mr. S. Beeson, Dr. Hermitage Day, and Mrs. G. Leigh Spencer, while it was also proposed to add the name of Mr. C. T. Pulley, M.P. Mr. A. Lovesey was also unanimously re-appointed hon. secretary and treasurer, with Mr. W. Davies as hon. librarian, Mr. S. Beeson hon. lanternist, and Mr. A. C. Slatter hon. auditor. On the council were elected Mr. W. Robinson, Mr. W. Williams, Mr. W. Davies, Mr. E. G. Davies, Mr. W. A. Grosvenor, Mr. A. Naylor, Mr. S. Beeson, Mr. J. Porter, Mr. A. G. Turner, Mr. J. H. Stooke, Mr. W. Marchant, Miss McAdam, and Mr. Devonport.—It was stated that two winter evenings and three summer outings would, if possible, be arranged, and now that the war restrictions had been removed from photography it was hoped that the members would display an increased enthusiasm, and that a brighter season was in front of the society.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—At the last meeting, the chairman, Mr. F. Creighton Beckett, entertained his fellow members with his lecture "The Experiences of a War Photographer." He described his endeavour to obtain a position in the Flying Corps and how he ultimately went to the front as an official photographer. His description of the war, in conjunction with some 200 slides, revealed many phases which were entirely new to most present. His photographic equipment was truly a formidable one, a six foot step-ladder stand, a full view Eastman stereoscopic camera, plus two cases containing thirty-six 8 by 5 double slides. Work behind the lines was fairly easy, but to go over the top and take photographs of advancing troops required some nerve. Incidentally field hospitals in full operation were shown, also a quaint horse hospital inside a disused sugar boiler. The lecturer's slides of Hun shells bursting in mid-air were decidedly interesting, as was also his description of plate changing in dug-outs. Mr. Beckett has made journeys in tanks, balloons, aeroplanes, and on foot. He showed slides taken from varying altitudes, and also of U-boats. The War at home proved equally interesting: his slides included "Baby Killers," and records of air raided and bombarded districts. Mr. Beckett seemed to have photographed nearly everything from U-boats to field kitchens, the King, General Staff, down to Tommy home on leave.

NEW PHOTOGRAPHS OF THE TROOPS.—The Committee of the Imperial War Museum has taken over the control of the official photographers in various theatres of war. These photographers are of three descriptions, namely:—(1) Operators who, for a long time past, have taken the official photographs which have appeared in the daily Press. (2) Newly appointed photographers who will take portrait groups of the troops in France. One of these operators will be allotted to each Army. (3) Newly appointed operators to take photographs for the Records purposes of the Imperial War Museum. There will be about seventy of these operators employed in France, and arrangements are also being made for the appointment of operators in North Russia. Prints of the photographs taken under (1) can be inspected and copies bought at the Imperial War Museum, Photographic Section, 10, Coventry Street, London, W.1. Prints of the photographs taken under (2) and (3) will be obtainable in the same manner as time and circumstances permit. Arrangements are being made for the purchase of photographs taken under (2) by soldiers in France. They will be obtainable at a low cost. The Imperial War Museum has five photographic exhibitions running in the country.

DEVELOPER POISONING.

To the Editors,

Gentlemen,—I understand an article appeared some time ago with reference to skin poisoning by metol or amidol. I did not see the article, but I understand the writer said there was no known cure for the complaint. Will you permit me to give my experience on this subject? I have been a victim of metol and amidol skin poisoning for over 18 years all over the fingers and arms. I have attended doctors both in England and Scotland, but with little benefit. I saw Ujah ointment advertised in the "Journal," and tried it. What surprises me now is that the doctors did not discover this ointment before this, because to me it has been a miracle, and I would ask every man and woman suffering from this dread complaint to write to the Ujah Ointment Company, and I take upon myself to say that if they fulfill their conditions in the using of it, it will prove a miracle to them as it has been to me.—I am, yours,
OPERATOR.

WASHING PRINTS.

To the Editors.

Gentlemen,—I notice a reference in this week's "Journal" to washing prints. If photographers would only do as I do they would have no further trouble. I have an ordinary photographic sink with plug. The only extra expense is for one clothes-peg, American pattern, best without metal top, and one ordinary cheap clamp with screw. Put the thin end of the clamp into the clothes-peg, just fix it in, then put the clamp and peg on to the edge of the sink, clothes-peg side inside the sink—most photographers have a piece of tubing to the tap—then put the free end of the tube into the bottom of the clothes-peg, turn on the tap, and you have a good whirl of water all round the sink. To empty the sink, put an ordinary 2-lb. jam jar over the plug with a small piece of wood to keep it off the ground, and when the sink is full it will act as a syphon and will fill and empty itself until further orders. It will do for postcards or large prints. I test all mine with permanganate, and if it is occasionally looked at to see that the tap is running at the right force to fill and empty itself it is the best I have ever used.—Yours truly,
A. ENGLAND.

50, High Street, Barnet.

THE MERCURY VAPOUR LIGHT

To the Editors.

Gentlemen,—Referring to the article on "Artificial Lighting" in this week's "British Journal," may I be allowed to point out a correction concerning the use of mercury-vapour lamps? The statement that the ghastly appearance which this light unfortunately has "may be overcome by hanging a thin pink curtain in front of the tubes" is misleading. Mercury vapour giving a minus-red light, hanging up a thin pink curtain will have no more effect than hanging up a dirty duster, for both would have much the same appearance, it not being possible to see red by this light. There is one exception, however, in the case of rhodamine, which is a scarlet dye. Reflectors coated with a varnish containing this dye have the mysterious property of supplying the missing red, so that a more or less white light results. Cardboard so coated used to be obtainable at a cost of something like 7s. per square foot.—Yours,

STANLEY BEAUFORT.

Elliott and Fry, Ltd., 55, Baker Street, February 8.

["Practicus" writes that he is quite aware of the theoretical uselessness of the pink curtain, but that, as it happens to answer the purpose, he advocates it. It was first suggested by Mr. A. Langfier about twelve years ago, and since then has been successfully used in many studios. Pink nun's-veiling was the material used.—Eds. "B.J."]

BRITISH AND GERMAN LENSES.

To the Editors.

Gentlemen,—I have read with great interest your editorial article with reference to "German and British Lenses" in your issue of the 3rd inst. You have touched very forcibly upon a very important point. There is a legend in the minds of at least nine out of every ten users of cameras in this country that German are superior to British lenses. It has often in the past taken a very strong light of scientific truth to break through the gloom of superstition. This false doctrine of German superiority must be dispelled, so let us have the necessary light in form of statements of fact such as some of those appearing in your article. Why cannot the facts regarding the merits of British lenses be gathered together and published in a popular way in the lay press? The technical press is read by too few of the public. Very few camera users ever read a photographic journal. I urge you not to permit the question to drop, but to keep it in the forefront until this objectionable legend is utterly dissipated. May I suggest that much of the advertising matter of British makers could be improved? It so often seems flat, and lacks force. Why not make it more real? Is any progress being made? Then tell us in a few words wherein it consists. This country longs to do business in fine goods with Great Britain. Can it not be shown that the goods are superior to any other? Let us have information.—Sincerely yours,

GEORGE C. CAMPBELL.

Toronto, Canada.

"CINEMATOGRAPH" OR "KINEMATOGRAPH."

To the Editors.

Gentlemen,—It is gratifying to note that the "B.J.," with its usual keen sense of the fitness of things, has never been misled into spelling the words "cinematograph" and "cinematography" with a "k."

The first use of the word cinematograph was by our French allies (M. Bouly, in 1892, and M. Lumière, in 1895), and these, of course, spelt it with the much pleasanter-looking and more English "c." It was, in fact, the "cultured" Teuton who began to write motion pictures with a "k."

Some etymological purists may object that the word cinematograph comes from two Greek derivations—*kinema*, motion, and *grapho*, to write. Well, what of that? There are many other English words, also formed from Greek roots and beginning with or containing "k," which no educated person ever dreams of spelling save with a "c." How ridiculous, for instance, the following sentences look, in which a few such words have been spelt in strict agreement with their origin! "The deakon suffers from kolic, due to watching komets and eklipses in the teleskope on the Oktagon. He has been ordered to a warmer klimate, to go in for kykling and akrobatics; but, above all, to keep out of the krypt and the katakombs, or, as a klimax, he may fall into a kataleptic state and need more kaustik treatment." Yet, either the foregoing "howlers," suggestive of a third-standard examination in a council school or of so-called "reformed" spelling, are entirely correct, or else "kinematograph" must be wrong. One cannot have it both ways.

No reflection whatever is intended on any person, periodical or text-book, that has hitherto, perhaps thoughtlessly, used the "k" instead of the "c." But surely, in the light of some recent happenings, there is little excuse left for preferring an essentially Germanic orthography to one supported by the best British, French, and Latin precedents.—Yours faithfully,

A. LOCKETT.

THE ASSISTANT QUESTION.

To the Editors.

Gentlemen,—Judging by the correspondence which has appeared in your columns under the head of "The Assistant Question," there seems to be a general consensus of opinion that better provision should be made for the training of photographic assistants, although there is naturally considerable difference of opinion as to the best means of attaining this end.

It appears to me that the proper body to undertake this work is undoubtedly the P.P.A., but, as far as I am able to judge from the reports of its proceedings, the council of that association, although

it has admittedly done, and is doing, excellent work, is not fully alive to its duties and opportunities in that direction. I, for one, should like to see the Association provide or assist in providing, proper training facilities in various branches of photographic work, in London and other large centres.

I should like to see examinations held periodically in London or elsewhere if required, and certificates of efficiency granted to successful candidates.

This, and other possible extensions of the work of the Association, would probably involve the employment of a full-time secretary and the provision of a central office; supplemented, if thought advisable, by voluntary district secretaries in various parts of the country.

The Association might, in my opinion, be very much strengthened and its constitution be more in accordance with modern democratic principles, if it were opened, under certain conditions, to assistants as well as employers.

It might be advisable to confine the membership, as far as new members are concerned, to those who have obtained a certificate of efficiency under the above suggested examination scheme. The new condition of admission to membership not coming into force for twelve months, in order to afford the established photographers who had not hitherto joined the Association, but who might feel disposed to do so in view of future developments, an opportunity of becoming members without examination.

A possible extension of the scheme might be the annual election, either by the Council or by the whole of the members, of Fellows of the Association, in consideration of exceptionally high standard of work, or of services rendered to the photographic profession.

It would be obviously impossible to carry out such a scheme on the present totally inadequate subscription, which it would probably be necessary to raise to at least £1 la. to employers and, say, 10s. 6d. in the case of assistants.

Hoping that these quite tentative suggestions will give rise to a useful correspondence on the subject.—Yours faithfully,

G. E. HORTON

55, Fort Road, Margate.

FORTHCOMING EXHIBITIONS.

February 10 to 22.—Glasgow and West of Scotland Amateur Photographic Association Inter-Club Exhibition. Secretary, Gilbert S. McVean, 125, West Regent Street, Glasgow.

February 20 to 22.—Leicester and Leicestershire Photographic Society. Secretary, H. C. Cross, 80, Harrow Road, Leicester.

February 22 to March 8.—Edinburgh Photographic Society. Entries close February 13. Secretary, George Maasie, 10, Hart Street, Edinburgh.

April 17 to May 22.—Hammersmith Hampshire House Photographic Society Annual Exhibition. Two open classes. Entries close March 13. Joint secretaries, J. G. Abrahams, 41, Hamilton Terrace, London, N.W.8; A. H. Page, 12, Lime Grove, London, W.12.

SNOWDEN WARD MEMORIAL FUND.—Mr. J. C. Warburg informs us that he has received a report of the fund from Mr. Morris, House Governor of the London Hospital. So far, no calls have been made upon the fund, the balance of which available for distribution now stands at £60 ls. 2d., made up as follows:—1913 to 1917, income as account rendered, £52 19s.; 1918, dividends received, £5 6s. 2d.; income-tax recovered, £1 16s. Total, £60 ls. 2d. Mr. Morris does not anticipate that this will be the case indefinitely; meanwhile, the fund increases gradually, in readiness for future contingencies. The capital remains in £180 Central London Railway stock at cost, £153. Mr. Warburg calls the attention of photographic and philanthropic societies to this fund, which is available to help any needy photographer who is an in or out-patient of the London Hospital, for purposes to which the ordinary income of the hospital is not applicable. The almoners of the hospital may, for instance, apply it towards rent, or strengthening food, or a stay at the seaside after treatment at the hospital itself, or for other beneficial purposes, within their discretion. The word "photographer" above includes a wide number of cases.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

A. P.—Messrs. Griffiths Steam Works, 26-31, Eyre Street Hill, Hatton Garden, E.C.

N. E.—There are only two outfits made—the "Powerful" of Messrs. Kodak, Limited, Kingsway, W.C., and the "Howellite" of Messrs. John J. Griffin and Sons, Limited, Kingsway.

E. W.—We should distrust the pyro for development, but would recommend you to make up 20 ozs. according to your usual formula. If it develops satisfactorily there will be no harm in using it.

T. N.—1. If there are no rights of reproduction an average price for 4-plate prints would be, say, 2s. 6d. each. 2. For the right to reproduce the photograph once only in a book or periodical, the charge would be 10s. 6d. per photograph.

H. E.—The Koresko is what is termed a daylight enlarger, and can be used with any ordinary lens. The cost price for the 15 x 12 size was about £3 3s., including lens. Its present value would be about 35s.

G. D.—There is no published formulae so far as we know for hydroquinone in combination with Rodinal. Generally speaking, Rodinal is added to hydroquinone at the time of use in quantity sufficient to give the more rapid development of detail which is the characteristic of Rodinal.

W. J.—The maximum aperture would be $f/3$, provided that the supplementary lens is at least equal in diameter to the original front lens. The addition of the supplementary lens would interfere with the definition to a considerable extent, and it would probably want stopping down to $f/16$ to be usable.

C. J.—The specimen print has the look of a red chalk image which has somewhat faded. The usual method of getting such results (they need not necessarily be fugitive) is by first sulphide-toning in the usual way with the ferri-cyanide bleach, followed by soda sulphide, and then toning for a shorter or longer time in an ordinary gold sulphocyanide bath as used for P.O.P.

G. E.—1. Little to choose between the two patterns. We should say the single metal slide (as it was obtainable before the war) is a better-made article than the wooden slides. Of course, if your slide is not a tight fit, you are bound to get fog. 2. Yes, a very good lens. 4. If you are using the camera for all kinds of purposes, for instance, copying, a double extension pattern will be much the best.

W. B.—The usual plan is to set up the titles in type, or to draw them in ink on a large scale and to photograph down to the required size. If they are required white on black, the negative is then cut into strips while on the glass, and the strips

transferred to the landscape negative by the usual method with hydrofluoric acid. Or you might print a positive transparency which will give you black letters on a white ground.

J. H.—The distance between light and condenser is variable according to the degree of enlargement, about the diameter of the condenser is an average distance. The negative should be put as near to the condenser as possible, $8\frac{1}{4}$ inches will then only barely cover the half-plate. You can use a 50 c.p. globe, but it is rather too large in area. Try to get one of the smaller half-watts.

T. C.—A good furniture polish such as Adams's will answer for the woodwork unless it needs a varnish, in which case you would have to use French polish. There is a varnish called liquid veneer which puts on a good gloss. For the leather, a little olive oil will freshen it up if not in bad condition. If the surface is gone, you should use one of the ready-made revivers such as Nuagane, which is made in various colours.

H. W.—The only advantage of an electric dry-mounter is that it is free from the fumes of burning gas, and that it does not call for the attention as regards ventilation that a gas-heated dry-mounter does. It is more costly in use than gas at ordinary rates of electric supply, and the resistances are liable to wear out, whilst connections may also go wrong. We do not think there is much difference in the speed of heating up, and are unable to give you any reliable figures for second-hand prices of these goods. There is no doubt the gas model is much the better.

G. B.—We think the best reproduction process for your landscape photographs would be machine photogravure. You should write to Messrs. Vandyck Printers, Limited, Park Row, Bristol, for quotations for work of the kind which has figured as frontispieces to the "B.J. Almanac" for the last two or three years. Next to this is collotype, two firms doing which are Messrs. Waterlow and Sons, Broken Wharf, London, E.C., and the Photophane Company, Cranfield Works, Brockley, S.E.4. The specimen you send is ordinary half-tone, one of the best firms for which is Messrs. Hood, Limited, St. Bride Works, Middlesbrough.

W. B.—The only formula we know of for a combined developing and fixing solution for ferrotype plates is the following, published some years ago by a German maker of these plates:—

Soda sulphite, cryst.	31 parts.
Hypo	248 "
Soda carbonate, cryst.	8 "
Potass bromide	8 "
Water	800 "
Hydroquinone	20 "
Ammonia (sp. gr. .91)	45 "

PETZVAL LENS.—I have the component lenses for several Petzval lenses (three different foci sets), which I want to mount up for my own use. I do not know, and cannot seem to find in my books the formulae to determine the separation and position for stop. Could you kindly furnish this?—A. H. B.

The amount of separation in such lenses is not a definite quantity, but is the result of a compromise between astigmatism and roundness of field, the former being in excess on a long tube and the latter on a short one. This you must settle by trial, starting with the average length for the sizes of lens you have. The stops may be placed midway between the combinations.

BLEACH FOR BROMIDES.—I notice a formula in your 1918 Almanac for outlining drawings from bromide prints, etc., which consists of the following:—

Thiocarbamide	240 grs.
Nitric acid	4 drs. (fl.)
Water	20 ozs.

My dealers inform me that thiocarbamide, being a German product, is now unobtainable, and they know of no suitable substitute. Can you kindly tell me if there is any other process by which to produce the same result?—H. K.

The silver image of a bromide print should be bleached entirely away, leaving the inked drawing, by means of a mixture of iodine and cyanide. Make a 10 per cent. solution of iodine (in potassium iodide) and potass cyanide, adding about half a drachm of each to

1 oz. of water, and if the solution does not bleach as energetically as it should, add more of the cyanide.

O. A. W.—1. (a) The bisulphite solution is sold by Lumiere. The instructions refer to that, though the solution as sold by other makers, such as Johnson's, probably does not differ materially from that. We do not know what is the relation of the solid bisulphite to the solution. (b) We cannot understand your query. (c) No objection that we can see to masking down Autochrome pictures. (d) Dissolve in distilled water and keep in the dark. 2. The usual practice is certainly to mount on canvas and to mount the canvas on a stretcher. We should not think that canvas between print and mount would give a canvas effect. 3. None that we know of. 4. Water-colours are certainly easier, and for a certain class of work—light effects—more popular, though we should say that a great many more enlargements are sold coloured in oils than in water-colours. 5. The more transparent brown image renders the print considerably more amenable to colouring. 6. The only alternative is the special filter sold by Zeiss and possibly obtainable from second-hand dealers. It obviates reversal of the focussing screen.

MR. J. R. CRISP, late manager to Messrs. Sichel and Samuelson, having recovered from wounds received on active service in France, is now rejoining the firm in the capacity of representative for the Midlands and North of England in place of Mr. Extine, now no longer associated with the firm.

SOCIETY OF MASTER PHOTOGRAPHERS (Lancashire and District).—The first dinner in connection with the Society will be held at the Albion Hotel, Piccadilly, Manchester, on Tuesday, February 25, at 5.45 p.m. An excellent musical programme has been arranged for 7 o'clock to 9.30 p.m., thus enabling members to reach home in good time. A satisfactory response has been received, but a few more tickets are available, and may be had by making early application (the accommodation is limited) to the Hon. Sec., F. Read, 14, Balfour Road, Southport. A general meeting of the Society will be held at 4.30 p.m. on the same day, February 25, at the Albion Hotel, Manchester.

The British Journal of Photography.

IMPORTANT NOTICE.—Advertisers are requested to notice that the prices printed below represent an

Increased Scale of Charges,

which is now in operation in respect to all line announcements.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind this revised tariff. They will thus save themselves delay in the publication of their announcements.

Net Prepaid Line Advertisements.

Increased Tariff of Charges.

12 words or less	1/-
Extra words	1d. per word.

(No reduction for a series.)

Special Note. Adv'ts under a Box Number.

"Box No." and office address charged as 6 words.
For forwarding replies add 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.
Orders to repeat an adv't must be accompanied by the advertisement as previously printed.

Advertisements are not accepted over the telephone.

The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.

Displayed Adv'ts should reach the Publishers Monday morning.

The insertion of an Advertisement in any definite issue cannot be guaranteed.

SUMMARY.

In this week's article "Practicus" deals with accessories and furniture. He believes that the day is not distant when portraits will again be relieved by the judicious use of these appliances (P. 83.)

At the last meeting of the Royal Photographic Society Mr. S. R. Williams described a method of making colour prints on paper. He makes a negative on the well-known Joly system, and by means of a special masking plate cuts out two of the three elemental colour lines; from the remaining one he makes a bromoil transfer, which is transferred to drawing paper. The other two colour-sensations are treated in like manner. (P. 88.)

A long article on photographic surveying from the aeroplane is reprinted from the American journal "Aviation." The writer believes that in the future aerial photographs will be largely used for filling in the details of survey work, and sets forth the essentials of a camera suited to the purpose. (P. 84.)

The Edinburgh Society of Professional Photographers, at their last meeting discussed their education of assistants project, as well as the fixing of a minimum price for postcards. (P. 89.)

The question of the education of assistants is discussed in a leading article, in which we point out the necessity of training being started immediately the prospective photographer leaves school. (P. 82.)

Many people imagine that when a patent has been granted to them they are secure against infringements. This is not the case, as the official search for anticipations only extends to previous specifications. This point is dealt with on page 82.

A claim for the spelling of cinematograph with an initial "K," screening the mercury-vapour light, a maximum day for dark-room workers, and the hydroquinone-rodinal developer, together with letters upon the assistant question, fill our correspondence column. (P. 91.)

The amateur lecturer who wishes to discourse on photographic technique and history is often at a loss to obtain his material. We indicate a few sources of information on page 81.

Studio construction, enlarging without condensers, lens matters, and stains for picture frames, are among the subjects touched upon in "Answers to Correspondents." (P. 92.)

We point out the unreasonableness of some of our correspondents who write to us complaining of the quality of prints and enlargements advertised at very low prices, expecting to receive work of equal merit with that of first-class firms. (P. 81.)

A very practical lecture on toning bromides was given by Mr. H. S. Newcome at the Croydon Camera Club. Many interesting points were raised at the subsequent discussion; a formula for red chalk toning, which differs somewhat from that generally used, was given. (P. 89.)

EX-CATHEDRA.

Low-Priced Trade Work. In a business such as photography, in which the goods sold to the public exhibit so wide a range of quality, it is, of course, natural to find a similar range of quality in the work done by trade firms for photographers. In both cases the quality is more or less accurately reflected in the price which is charged. A consideration of these facts should, we think, provide the answer to those who now and again urge upon our publishers that they should exclude the very low-priced firms from our advertising pages. An order for enlargements to one such firm may have been executed in what the disappointed maker of the negatives angrily calls a "disgraceful" style, on the strength of which, and without showing either the enlargements or the negatives supplied for them, it is protested that the firm should not be allowed to advertise its offers of service. As we have said, a complaint of this kind can only be made in the absence of a comparison between the price which has been paid and that charged by firms of the first or even the second grade. Probably the chief difference between low-price and high-price firms—a more essential difference than poorer materials and cheaper labour—is that their scale of prices does not allow them to repair defective work by doing it again. They send their first production unless its defects are too gross even for their standard, and hence the result is very largely a matter of chance. Like the little girl, and dependent on the negative, it may be very, very good or it may be horrid. If it be the latter, the purchaser must surely think that he could hardly expect anything else at the price. His case is paralleled by that of anyone who puts money in a high-yielding investment: he is buying something cheaply priced, and he takes his chances on it. No doubt the advertiser announces that his work is first-class, but then what advertiser does not?

* * *

A Lecture on Photography. Perhaps it is a welcome sign of greater general interest in technical and scientific matters, perhaps the result of the searchlight prominence of photography in the war, but we have lately received quite a number of requests that we should name the book to be recommended to anyone anxious to deliver a popular lecture on photography. The fitness for his purpose of a would-be lecturer who finds it necessary to put the question may be doubted, but at any rate the inquiry exhibits a praiseworthy desire for information, and doubtless there are many with a thorough practical acquaintance with photography who are not too self-confident to see that much more is demanded of a lecturer on the subject. For such as they a book which provides a serviceable basis of information is Mr. Chapman Jones's "Photography of To-day," a volume which reviews past and present photographic processes in a popular yet scien-

title way. On the very earliest history of the art, that is the work of Niépce, Daguerre, and Talbot, reference may be made to a series of papers which ran through "The Photogram" for 1900. There are one or two issues of "The Photo-Miniature" which will usefully provide material, viz. those on "Who Discovered Photography?" "Colour Photography," and "Aerial Photography," and as a means of taking a bird's-eye view of the successive stages of photographic progress there is the monograph "Photography, Past and Present" issued as an illustrated supplement to the Diamond Jubilee Number of the "British Journal."

Focussing Sharply.

In focussing originals, such as paintings, in which the absence of definite outlines presents a difficulty, most photographers make use of a small printed card placed against the surface of the original in order to provide a workable test object. But perhaps it is not so generally recognised that different types of lens require different treatment in order to obtain the best results. As a rule, rapid rectilinears and other lenses possessing greater or less roundness of field give the best average sharpness when the test object is placed so that its image falls about midway between the margin and centre of the field. With most anastigmats it is best to obtain the greatest sharpness in the centre, and the margins will then frequently be sharper in the negative than they appeared on the screen. With all types of lenses great assistance can be given by a judicious use of the swing-back, both vertical and side movements being employed as needed. This is particularly the case when using a portrait lens at its full aperture; a swing of the back will allow of the same degree of good focus over the plate as could be obtained by a smaller stop. The method must not be abused, particularly when a short-focus lens is being used, otherwise the size of hand and feet in the sitting figure will be unpleasantly exaggerated.

Patent Specifications

A correspondent who addresses a query to us raises a point which no doubt is now and again in the minds of many other readers of these pages. It is a matter of common remark that the published specifications of alleged inventions to which patent protection is granted are often things which are as old as the hills or, on the other hand, bear on the face of them certain practical disabilities. But the explanation lies in the fact that the preliminaries in the way of search which are carried out before the granting of the patent extend, not to books and periodicals where the invention very likely has been published, but only to patent specifications themselves issued during the period of fifty years prior to the date of application. Moreover, the Patent Office is not concerned with the efficiency of an invention. It takes the applicant's word for its merits in this respect. Apart from its search in prior specifications its work is not very much more than a registration of the description of the invention and the claims made in respect to it. The questions of efficiency and of prior publication are left to be the subject of investigation in a court of law in the event of any action being taken as to infringement. While there are thousands of existent patents which have not been the subject of this legal inquiry, it is nevertheless true that a patent has not received absolute certification of value until it has been examined in the Courts. Inventors of photographic appliances should not therefore set too high a value upon the fact that they may have been granted a patent for a particular appliance. Nevertheless, it is a wise and not very expensive precaution to spend, say, the matter of five pounds on obtaining protection for any invention before offering it for

sale to a commercial firm. The patent rights can then be disposed of, and the cost of maintaining the patent defrayed by the purchasing firm if such is considered advisable.

THE EDUCATION OF ASSISTANTS.

OUR title has nothing original about it, it has figured pretty frequently in the "Journal" lately, but as the question seems in rather a nebulous state, it is perhaps in order to inquire what it really means. In other trades it is not usual to employ the wide and comprehensive term assistant, but to specify the branch in which the employee is to be engaged. In letterpress printing, for example, we have compositors, linotype operators, machine minders, and warehousemen, and in each division a man is only expected to be proficient in his particular work; but in photography, except in very large establishments, this is not the case, and an assistant is expected to be able to turn his hand to any job which happens to come in his way, or in other words, if the reputation of the studio is to be kept up, to be as good an all-round worker as his principal and a better one in some particular section. That there are such assistants we very well know, and the photographer who secures the services of one is to be congratulated.

Now before starting any education scheme it would appear to be necessary to define the various classes of assistants and to set up some standard of proficiency for each. Another important point to be settled is that of remuneration, so that a youth or girl entering the profession should know what wage can be looked forward to when he, or she, has qualified as proficient. Many things besides scientific knowledge and practical proficiency are called for in everyday work. We have known amateurs capable of turning out prints which would do credit to any studio in the kingdom, but their pace has been hopelessly slow, and no employer could afford to keep them. Nothing but practice in a busy place can give the necessary smartness, and it is a question how this is to be obtained.

The old practice of engaging a juvenile as a sort of messenger and general helper with more or less opportunity to pick up a knowledge of photography will obviously be out of the question under the new régime. Proper teaching should start at the outset, and it is difficult to see how this is to be obtained in many localities. Let us take the case of an intelligent lad living in a small country town who wishes to become a photographer. The only course that is open to him is to obtain work in the local studio with a man who can just manage to make a negative and print it sufficiently well to pass muster with a not too critical class of customers. When the lad begins to want a living wage he looks further afield, only to find that he is one of the incompetents whose existence we all profess to deplore, but who provide a source of cheap labour for the sweaters who, as in all other trades, are found in photography. If we are to have well-trained assistants there must be sufficient inducement for them to be trained in the same way as chemists, engineers, lithographers, or dental mechanics, by a proper system of apprenticeship or pupilage, supplementing their workshop practice with a part-time training in the scientific aspect of their work. The latter cannot be given in a house of business without serious waste of time, so that something on the lines of the Fisher scheme of education must be adopted, and it is for the masters to co-operate with the local authorities to secure this. But such a scheme is only workable with very young people; after the age of eighteen it is very difficult to find that readiness to assimilate knowledge that is natural to the schoolboy. It is easy enough to teach youngsters of fifteen to eighteen such subjects as elementary chemistry, optics, or even art principles, but

if those three precious years have been wasted, the mind takes another turn, and learning becomes laborious. Moreover, a bad way of working is acquired, and this is often felt to be sufficient. There is now also the sex question to be considered, as a great change is coming over photography by the invasion of women into almost every branch. Are the assistants of the future to be male or female? Already men returning from army service are finding that situations are not so easily obtained as they had expected, and we look for still further developments in the same direction. Only a few years ago, and women were considered as greatly inferior to men as retouchers. What is the position now? The same thing is going on in other branches—printing, dark-room work, and even in studio operating—the only field in which male labour is unchallenged being that of outdoor work.

Still, male or female, we must have assistants, and the initiative for their training must come from the master photographers. Their first problem will be to find instructors, the second to find a body to hold examinations and grant certificates of such a degree of proficiency that the holder can secure a standard wage. In the organisation of the chemists and druggists we have an excellent model. In this profession a youth enters as an apprentice, is given time for study, usually takes a course under a coach, and finally passes his minor and major examinations before he can hope to attain a position as a "qualified assistant." One of the greatest factors in producing a shortage of good assistants is the ease with which a competent worker can start on his own account in a small way. If we can offer such terms as will keep good workers in their situations we shall have accomplished much.

PRACTICUS IN THE STUDIO.

STUDIO ACCESSORIES AND FURNITURE.

IN no respect does the modern style of studio differ more from its predecessors than in the matter of accessories, and we might treat the former in the same way as did the writer of a book on Iceland. A chapter was headed "Snakes in Iceland," and the chapter consisted merely of the words, "There are no snakes in Iceland."

When we speak of accessories it recalls to the old operator the wonderful combination sets in papier mâché on a wooden foundation which gave pedestals, balustrades, stairs, bridges and a host of other things as they happened to be arranged, or the equally wonderful pieces of furniture which professed to represent a piano, a writing-table, a bookcase, and a seat, and deceived nobody. Then we had rocks, stone walls and loose boulders which were sometimes useful, not to mention ships' masts, boats, and swings. These have now, happily, found a resting-place in the lumber-room or have helped to relieve the shortage of coal in these upside down times. Still one cannot but help feeling that the accessories themselves were not alone to blame for artificial-looking pictures, the unintelligent and mechanical way of using them being equally to blame. I believe it to be possible that we shall again revert to the use of more accessories in the true sense of the word, when someone finds it necessary to be "original" and to produce something to relieve the severe simplicity of the head and three-quarter length portraits which are now the vogue. The modern portraitist is not likely to fall into the errors of his predecessors, as he has learned to concentrate the interest in his pictures by subordinating unnecessary detail and would not think of making a negative in which the surroundings were as brilliantly lighted and as sharply defined as the figure itself. Although they are somewhat out of favour at present I must confess to a liking for full-length figures, and it is difficult to get these well balanced without introducing something to give the needed spot or mass of light and shadow which makes the composition complete. This is, of course, widely different from the old practice of building a zereba of plants and vases round a lady's figure, so often done by the bygone masters of our art.

A safe principle for the guidance of those who have to equip a studio is to follow the advice of Ruskin and to have "nothing except what you know to be useful or believe to be beautiful." Do not buy settees or chairs which no sane person would ever admit to a dwelling-house, but select every piece of furniture, whether intended for the studio, the reception-room or even the dressing-room, with a view to its suitability for inclusion in a picture sooner or later. Variety, it has

been said, is the spice of life, and variety in your work can be more easily secured if there is an ample choice in the matter of furniture. You will then steer clear of the error made by an American photographer whose confession I read a few years ago. He specialised in children's portraits, and when the twisted wicker chairs and settees were introduced invested in a fine specimen. Needing a new window display, he made a large canvas-covered panel, and fixed upon it a score or so of his latest and best productions. It was set up in the window and he went outside to judge the effect; when he viewed it he said that all he could see was twenty wicker settees with babies on them. A sadder and a wiser man, he went inside and promptly dismantled the show from which he had anticipated so much.

Much of the charm of "home portraits" is due to the natural posing and the judicious inclusion of furniture and ornaments which are associated with the sitter in the minds of his friends. A scholar taken in his study appears more at home than he does against a plain dark background, and in the case of people who, as an old friend of mine said, "are more distinguished by their facial peculiarities than by actual beauty," there is a real advantage in having something beside these "facial peculiarities" to rest the eye upon. In studio portraits therefore we should endeavour to reproduce the home atmosphere as nearly as possible and to avoid giving the impression that the whole thing is a make-up. If it be desired to make a picture of a man at his writing-table, the general idea seems to sit him at a small polished table with one or two pieces of paper and a small ink-bottle and pen borrowed from the reception-room. Such an arrangement is little better than the Oriental method of arranging theatrical scenery, in which one painting does for all the scenes, with the addition of a label to tell the audience whether it is a palace or a forest.

When selecting chairs or settees they should be chosen not for the beauty of their design when empty but for their appearance with a person seated in them. It will frequently be found that the arms are too high or that the curves are such that a graceful pose, especially of the forearm and hand, cannot be obtained. Many chairs are far too low in the seat and have either to be made up with loose cushions or by fitting rather high castors to the legs. It is, however, necessary to have some low chairs for short people, but with ordinary-sized sitters a better pose of the shoulders is obtained by using a chair rather higher than usual. Settees are best of normal height, as in them a more lounging pose is usually

wanted, so that all that is necessary is to avoid the special photographic patterns, except those of the garden-seat pattern, which are useful for sketch or outdoor effects. That much-maligned article the pedestal has had its day: it was hard-worked and has earned a rest. It has a useful successor in the flower or vase stand, which is very handy with standing figures, which would look a little lonely without it. It should never be used for the sitter to lean against, but with ladies' portraits may be used to support a bouquet or a vase of flowers which the sitter is arranging. It may also be used to hold the busby or helmet of an officer in full dress, to avoid the necessity of holding it in the hand or omitting it from the picture, to both of which there are serious objections.

Children's portraits permit of the use of many simple accessories, especially for outdoor effects. I made a very useful tree-stump of a lard bucket carefully covered with virgin cork, so as to give the effect of living bark, the lower ends being well spread so as to appear like roots. This with a cylindrical hollow "log" covered in the same way, afforded many excellent poses and did not look artificial. If the cork had been stuck on anyhow the things would have been useless. When working with these or other outdoor accessories a pail of coarse sawdust, the dirtier the better, is a great help. If a painted floorcloth be laid on the floor and the sawdust scattered over it, it looks like sandy earth and will show foot-marks, while it can be piled round the bases of such accessories as I have mentioned.

A baby-holder is an accessory which should be in every studio that is not exclusively devoted to adults. It may either be of the American or clip variety, in which the child's garments are caught in clips attached to an upright post, or it may be like a triangular seat with a low back and a hole through which the child may be held by a person behind. I have found a broad tape, which could be passed round the child's waist and fastened at the back of the holder, a very useful addition. Such holders are, of course, only intended for babies who can just sit up, and could not be trusted in an ordinary chair; besides, it permits the feet to be shown nicely.

Although I am more inclined to class them with apparatus, certain studio appliances are often called accessories. The head-rest is one, and one which I should be sorry to dispense with. Some care is necessary in choosing and handling this

instrument. In the first place it should not be heavy, and in the second place it should be simple. What is needed is a support which can be quietly placed behind the sitter (or usually stander), and adjusted so as to give the necessary steadiness. I may say that I rarely place the rest to the head, finding the shoulder or lower part of the neck to be a better position and less embarrassing to the sitter. The number of plates which are wasted on standing poses through "moves" by photographers who consider the head-rest out of date must be enormous. All the moving parts should be kept, like a rifle, bright and oiled where necessary, so that there is no jerkiness in action. Another necessary which I consider indispensable is the head screen. This needs no description, but the covering demands a few words. Most head-screens are covered with a sort of lawn, and this is generally useful; I have also tried light blue man's veiling, nainsook, and tracing-cloth, as well as butter muslin: these all have different light-arresting powers, and the user must choose for himself if he does not find the stock covering to his liking. A black gauze is sometimes used when it is desired to cut off light without diffusing it. Such a screen is very useful for toning down white draperies without losing the modelling. The reflector also needs no description. As far as its qualities go it should be light in weight, not too large, and capable of being adjusted to various angles. As a rule the surface is too light when purchased, but this defect soon disappears. When the surface gets very grey the material should be washed, but if it cannot be readily detached from the frame it may have a dressing of Blanco, a sort of pipeclay used by soldiers and for tennis shoes.

To revert to our original subject of accessories which appear in the picture, I would point out that modern printing and enlarging methods offer such opportunities for control that many of the old negatives which gave meretricious results in albumen or gelatino-chloride would give quite artistic prints upon rough paper with the sharp offensive lights toned down. Uniform sharpness throughout the negative is no longer considered as desirable, so that any falseness of texture in the accessories is not shown in the finished picture. Finally, do not overcrowd your composition; do not use more accessories than are needed. If not needed, do not use them.

PRACTICUS.

THE FUTURE OF AEROPLANE PHOTOGRAPHY.

The following article, which we reprint from our American contemporary "Aviation," very properly raises the question of the commercial future of photography in the air, in which there are certainly as great possibilities as in aerial navigation generally. The fact that one of the authors, Mr. L. J. R. Holst, is a camera designer and instructor should emphasise to manufacturers of apparatus the field which is opened by the application of aerial machines to practical methods of surveying.—Eds. "B.J."]

The commercial future of aeroplane photography is not generally appreciated by aeroplane builders, since they have not as yet realised that preliminary surveying of high-roads, railroad, and other through routes can be done quicker and more cheaply by aeroplane photography than by any other known method. This is largely due to the circumstance that cameras have been hitherto considered as instruments of mere detail in the aeroplane industry as a whole, while as a matter of fact they will probably become one of the most important factors in the development of commercial aviation.

The most fruitful field of commercial work for the aeroplane camera in the United States will undoubtedly be the completion of the topographic survey of this country, which work includes the complete detailing of maps not yet complete, as well as the mapping of territory which till now has not been charted at all. To this already extensive programme

should be added the locating of the high and low water lines along our coasts, besides work of more local interest, such as the production of correct maps of smaller communities for real estate records, the location of sites for dams for irrigation purposes, locating railroads and waterways through mountainous country, establishing aerial routes and emergency landings in vast wooded tracts, etc., all of which work can be done in a fraction of the time, and hence for a fraction of the cost entailed by a complete manual survey.

It should, however, not be understood that the aeroplane camera renders manual surveying obsolete. On the contrary, it is recognised that the camera does its most effective work in connection with the slower but extremely accurate work of the surveyor, each one being checked up by the work of the other. In fact, it may be stated that the camera furnishes the filling-in details to a degree of perfection not attainable—or, at any

rate, not obtained—by manual survey, whereas the latter produces a series of exact points of location which serve as control points for the data furnished by the camera.

To obtain useful commercial mapping results from an aeroplane requires different methods of operation than those used to make the so-called mosaics, because maps will be made between control points often many miles apart, between which it will be necessary to fill in not only the general ground plan but also the contour lines.

As a matter of fact, the mapping use of aeroplane photography has been to a certain extent set back by the war, for the reason that certain scientific views, which are not relevant to commercial photography, rather held the foreground. These were questions of emulsions and lens-openings, neither of which are really of as much importance as the purely mechanical sides of the problem.

Since all work enumerated before in this article is strictly of the order of map-making, only such photographic apparatus as is adapted to this class of work need here be noted. This excludes all hand-held or hand-operated cameras as well as any semi-automatic or non-automatic instruments which are rigidly attached to the aeroplane, since they partake with it in all its deviations from a perfectly horizontal position while in flight, a condition which is entirely incompatible with results for map-making. This leaves thus the freely suspended type of aerial camera for further consideration.

The military use of the aeroplane camera during the war has led to developments which do not necessarily form correct precedents, because of the assumption that an observer is essential. This has led to undue emphasis being placed on hand-operated or semi-automatic cameras, which were to be of such simplified construction that no imperfect functioning would occur under the hands of the operator-observer. These military conditions do not prevail, nor apply, in commercial aeroplane-mapping.

A division of opinion has existed relative to the automatic functions of aeroplane cameras among the Allied Governments, but in no case were these differences caused by the requirements of aerial photographic mapping.

Paramount importance was attached to the chemical side of aerial photography, much attention being devoted in particular to the perfection of colour sensitive emulsions, to more readily detect camouflaged objects from the real ones.

No doubt this aim is worth while, but since existing emulsions used with suitable ray filters were apt to produce, under the rough-and-ready conditions of actual field photography behind the lines, similar if not better results, with a far greater degree of likelihood to get any results at all, it must be regretted that these efforts placed the much more important mechanical side of the problem entirely in the shadow.

As long as the question of aeroplane photography was a question of filling in maps with nearby control points the detail design of the camera was not of the highest importance. To take a series of views over well-known ground is a problem comparatively simple, but commercial applications of aeroplane photography require more definite information in regard to drainage, divides, and general contour information, as otherwise the main benefits of rapid surveying cannot be obtained. Photographic aeroplane surveying will unquestionably be used largely as a supplement of the Photo-theodolite and other more common methods of surveying, to fill in between control points established by the older methods. But in the case of the more or less unknown country between control points established by the more common methods, and for such works as coast surveying, arises the greatest need of aeroplane survey.

Surveying to be done from an aeroplane, particularly for filling in large areas, must be obtained by means of an automatic camera. On considering the problem of commercial

aeroplane photography it will soon be possible to pick out the necessary elements of design, and why an automatic camera should be used.

All photographs to be used in map making must be a true horizontal projection of the earth's surface. In this way all points are practically reproduced by the photograph on a scale which is equal to elevation divided by focal length of the lens. If the plane of the photograph is not approximately parallel to the plane of the earth's surface (not considering the curvature of the earth), positions will not be correctly rendered; there is distortion to location which is equal to the cosine of the angle of inclination. In actual military practice, however, any camera installation which fastens the camera to the plane so that in the average flying position the camera is approximately horizontal was considered sufficiently good for purposes of making mosaics.

Contour Mapping

However, this is by no means an answer to the question of obtaining survey information, as in the case of obtaining contours from aeroplane photographs these can only be done by making use of the lens axis of the camera. The only way of establishing a true parallel position of the negative to the assumed plane of the earth is by means of the vertical position of the axis of the lens. Moreover, the only known factor for determining contours needed is the angular relation of the axis of the lens and its true focal length. With these two known factors the position of the earth can be graphically reproduced, and by ordinary drawing instruments a series of exposure points in the air can be determined. These exposure points are then used by transference of angles to reproduce graphically the location of points on the ground in space above or below the base line, which is usually taken at the foot of one of the axial points of the series of photographs.

To obtain a vertical position of the axis of the lens necessitates a free suspension of the camera in the body of an aeroplane where it is not affected by the air current in motion. This is easily done by putting the camera in the Gimbal suspension similar to a ship's compass. However, it is necessary to maintain a constant position, as otherwise the variation in the rate of motion of the aeroplane through the air would introduce a pendulum action in the camera. There are only two ways whereby this can be done first, the use of a gyroscope, and, secondly, the use of gravity and suitable air cushions to prevent oscillation, but at the same time to allow motion relative to the swinging plane. In practice the latter method is the better, as it introduces no mechanical complications, and the accuracy resulting is close enough for mapping purposes.

In addition to the requirements of angular position, aeroplane photographic surveying requires a large number of photographs in a single flight. It is next to impossible to change plate magazines or to fill holders in flight sufficiently rapidly to obtain an unbroken series; moreover, it is necessary that photographs should be taken at what is practically a constant interval between exposures; if not, there is very apt to be a break between two successive exposures which requires an additional flight to obtain the necessary information with which to fill the gap.

In a military sense, during the recent war, this matter was not of such importance as it becomes for photographic surveying, for the reason that usually photographs were wanted of a single spot only, and intervening places were not necessary, although at times desirable. This has led to the use of film cameras using roll films having as many as 100 exposures to each loading.

The principal difference between different makes of cameras for purposes of making military mosaics are usually matters of obtaining necessary power to change plates or film negatives.

Three methods of obtaining power have been used: the air fan, electricity, and spring motors.

In considering the design features of the camera it is very necessary to know to what extent photographic surveying will be carried out. If military mosaics are required, which generally are used simply to fill in small areas, a semi-automatic, regardless of form of drive—even a hand-operated camera—may be useful. If contour surveying is to be done it becomes necessary to have a very accurate timing device for the interval between exposures, as otherwise the overlapping relations between exposures will very easily be lost. The European continent is so thoroughly surveyed that the contour method has been very little used, and in the considerations of the necessary types of cameras, contour mapping has not been considered an essential feature. For this reason the so-called automatic or semi-automatic camera ordinarily in use is not completely automatic, but simply is a power-driven mechanism which changes a plate or film negative and in which the actual exposure is made either by the pilot or observer. There is only one completely automatic camera in existence which operates at varying rates of speed, controlled with certainty either by the pilot or the observer. This camera the Brock camera will be described later in detail.

The Triple Lens Camera.

When making flights for map-making purposes a given area of ground can only be fully covered if a number of flights in parallel courses are undertaken, each new flight following a course just overlapping the strip of land covered by the previous flight. The number of flights required to cover a given width of territory will then be directly proportional to the width of the strip embraced by the photographs, and consequently it is desirable to embrace as wide a strip of land as practicable in each view.

This consideration has led to the construction of triple lens cameras, the central lens pointing straight downward, and the lens on either side placed under an outwardly slanting angle. These three lenses are in one vertical plane at right angles to the direction of flight. The image-planes of the outer negatives are then usually set at an angle of 45 deg. to the central lens. These cameras are arranged for rigid attachment to the aeroplane. The two outer lenses will then produce pictures of strips of land extending far out at each side of the line of flight, whereas the central lens registers the views directly beneath the aeroplane and immediately adjoining regions.

Although this arrangement undoubtedly covers a width of territory not obtainable with a single lens, it introduces difficulties which seem to far outweigh its possible advantages, and at its best it is only suitable for use on fairly flat ground. The complications arising from three different planes of projection, and the necessity of afterwards reducing the two outer planes to that of the central one, without definite knowledge of the actual position of either plane at the instant of exposure, constitute serious obstacles to the usefulness and commercial adaptation of devices of this kind.

Timing Exposures.

It seems now preferable to obtain increased width of the strip of land depicted on the photograph by increasing its width and reducing the focal length of the lens, both to such limits as sound photographic and optical practice allow. A camera arranged to take negatives 5 x 7 ins., the 5-in. side in the line of flight, and equipped with a lens of 8 ins. equivalent focus, embraces at 5,000 ft. elevation on each picture a strip of land 4,375 ft. wide and 3,125 ft. long on a scale of 1/7,500, or, if elevated to 6,666 ft., would produce pictures on a scale of 1/10,000, embracing 5,833 ft. in width by 4,166 in length. Most of the high-grade lenses at 8-in. focus and openings of $f/5.6$ will

cut a 5 x 7 in. image sharp and without distortion, and are serviceable for such work.

The succeeding exposures should be timed at intervals of distance depending on the elevation and corresponding length of ground taken by the picture. The speed of the flight translates this distance interval into a corresponding time interval. It is thus desirable to provide means by which the actual time interval can be varied according to these conditions, and which will operate with dependable precision in its various adjustments.

As the manufacturers of the Brock Automatic Camera, it is probable that our actual experimental work in photographic surveying and in the design of cameras to obtain these results has been carried far beyond experimental work in this line by any individuals or by any of the Governments who have participated in the European war. The system of installation which we use has been found to permit exposures of from two to five times the exposure possible with any other system of installation, with all its attendant benefits. No other camera has been successfully built with a system of free suspension, with the result, also, that no other camera has been built which can also do contour surveying. The importance of contour surveying in a military sense was becoming recognised as the war drew to a close, and consequently this field of endeavour has had but a fraction of the effort put on it which will be devoted to it in the next few years.

Another feature of camera design which originated with the Brock camera was the use of film for military purposes. The Brock film camera has been made successfully to use film in two sizes: one 4 x 5 ins., using ordinarily a 12-in. lens, and one 8 x 10 ins., using a 24-in. lens, both types completely automatic. These cameras were the first ones used which entirely eliminated static electricity in the film, and are to-day the only ones in which static electricity never occurs. The system of obtaining large negatives on film without distortion through the use of a glass support originated with the Brock 8 x 10 in. cameras. However, the use of the large negative sizes will be confined to military purposes, as for commercial or ordinary Government mapping a very large scale is not required.

The Brock Camera.

Let us now consider some of the mechanical details of the Brock 4 x 5 in. camera and the reasons for the design. This camera is the outgrowth of a series of experiments to obtain a free suspension camera, motor driven, within reasonable weight, certain of operation, and controlled from a distant point, for use in a single-seated aeroplane.

Mechanical experiments led us into the design of the spring motor-driven cameras and resulted in our finding commercially feasible means of controlling the speed of operation of the spring motor not in any way dependent on friction. The entire engineering profession is aware of the difficulty of obtaining a satisfactory variable speed friction drive which includes both certainty of operation and certainty of speed. In the case of a spring motor this difficulty is emphasised because the control through friction must be done by the introduction of a governor. Such a construction results in absolute loss of control of speed regulation owing partly to the different percentage of friction due to moisture in the air in varying amounts. The system we use, therefore, is the control of the main spring motor by means of an auxiliary spring motor, which is in effect a clock with a speed regulation of $3\frac{1}{2}$ to 1. The importance of accurate speed control in the case of the Brock camera is greater than in any other camera, because of its ability to produce contour maps. Wherever it becomes necessary to obtain contours the axial point of the succeeding and the preceding negative must show on each exposure, with the result that exposures must occur at frequent and constant intervals without interruption, other-

wise a break in the sequence will partially destroy the value of the contour photographic flight.

Without any exceptions worth mentioning, all aerial cameras are fitted with focal-plane shutters, as the high efficiency of this type of shutter, together with its extreme mechanical simplicity, renders it superior to the between lens shutter. In the Brock cameras focal-plane shutters are provided with a fixed slot, the speed adjustment being obtained entirely by means of the spring tension. Speeds are variable from 1/50 to 1/200 of a second, or any similar range.

Shutter Speeds.

In connection with shutter speeds of aeroplane cameras it is of particular interest to mention that, owing to the almost complete absence of vibration obtained with the gimbal-suspension, shutter speeds can be regulated entirely with regard to the elimination of image movement through travelling speed, and no regard need be paid to the effects of vibration. The requirements due to speed are very easily met. For instance, a camera as already mentioned, fitted with an 8-in. lens, flying at 5,000 ft. elevation and at 120 m.p.h., requires no faster exposure than 1/20 of a second to give a sharpness corresponding to a circle of confusion of 14/1000 of an inch, and with a speed of 1/50 of a second the circle of confusion will be only 5.6/1000 of an inch. This means that the gimbal-suspension camera has the practical advantage of being able to photograph both earlier and later in the day than would be practical with rigidly suspended cameras, which are generally used with minimum exposures of 1/100 of a second to eliminate as much as possible the effects of vibration. It also means that such focal-plane shutters can be made with wide slots to reduce the duration of the exposure period, and thereby the resulting distortion, to a perfectly negligible minimum, which in turn eliminates the only seeming valid arguments against focal-plane shutters.

Evenness of Exposure.

A perfect evenness of exposure at all speeds can easily be obtained by proper design of the focal-plane shutter, in fact, so that the slightest difference in exposure plainly seen in aeroplane films, since maximum and minimum density adjoin in two negatives of a strip of continuous pictures side by side, will show no observable variation. Especially in civil or commercial uses of aeroplane photography do these various features come to their fullest significance, and it is only on this account that they have been mentioned in detail.

Summarising, the status and development of aeroplane photographic surveying is an art still in its infancy. Unless the aeronautical trade recognises the possibilities of this use of their product, and unless the engineering profession of the business realise its possibilities it is not likely that the growth will be rapid. It is an unfortunate fact that up to the present time the energy devoted to the constructive surveying features of aeroplane photography has been confined to, and understood by, only a few people.

The truth of the matter is that, in the first place, the emulsion questions which have arisen in Europe are really matters of no serious consequence, although a considerable amount of time and effort has been spent to change and to make special emulsions. Efforts have also been made in Europe to make emulsions sensitive to certain colours, whereas similar, if not better, effects could have been obtained with existing emulsions by the use of a colour screen and lengthened exposures. Whatever efforts have been made in the mechanical direction, they have been very largely in the direction of making a camera which could be operated by the average observer without any knowledge of photography or of mechanics. It is safe to say that if the motion picture industry which is now in existence had had a military use and military development, the present stage of perfection

would never have been reached, as the mechanical side of the motion picture industry has received a tremendous amount of attention for years. High-class motion pictures cannot be made by anyone but a skilled operator, and in exactly the same way the success of the future of aeroplane surveying is dependent upon operators learning about the necessary photography and mechanics of aeroplane cameras; but it must be recognised for the future of aeroplane surveying that apart from the development of the negative and the printing of the prints aeroplane photography is a matter which should be entirely in the hands of civil and mechanical engineers.

Aeroplane Photography and Commerce.

The modern aeroplane has reached the stage of development where the safety of operation and the certainty of operation are as good as of the average automobile of ten years ago. This means that an aeroplane can be used to fly for some hours over entirely unknown country without any landing places; it further means that such country can be completely and correctly mapped without difficulty and at a very low expense compared to the present-day methods of surveying. It is quite possible that in the future preliminary surveys will be made for railroads, roads, and various water-works entirely by aeroplane photography, and that when the line has been decided upon a party will go out simply for the purpose of staking agreed-upon lines. If the aeroplane industry will devote as much attention to this subject as has been devoted to other commercial possibilities, a rapid growth can be expected. As foundation-stones have been laid, it is only necessary for a general interest in this subject to be awakened by the aeroplane industry before its possibilities, first as a Government enterprise, and then as a commercial enterprise for civil engineers, will find general recognition.

Assistants' Notes.

Books on Colour.

ASSISTANTS who mean to make photography their profession should look into the question of colour, as pictorial art of the future will be intimately concerned in the study; some authorities—particularly those connected with the vast textile industry—declare the future is bound up with it. Students of painting are bidden to study nature secrets, but students of photography will find the scientific side profitable and to their liking. Since 1835 over sixty books have been written, a fourth of that number being published in London, a fifth in New York. The Americans, by their productions of the last ten years, promise to surpass us on all points—by numbers, high prices they command, complete range of subject, interest, and research. As all books of recent years seem to be written round Rood's "Modern Chromatics," students will do well to commence with that treatise, as it contains valuable information, clearly written, well illustrated with woodcuts and diagrams, but unfortunately has no colour plates to assist the text. This book having passed through many editions, a clean secondhand copy is more often seen than any other, and is worth looking out for.—BRUNINGTON.

A Reliable and Permanent Method of Intensification.

MANY photographers would be glad to banish mercury from their dark rooms if they could find a satisfactory substitute for it. Those who use the mercury intensifier know that they cannot depend upon the negative being any use in a year or so, and, although they have tried the chromium method, the danger of yellow stains has caused them to go back to the old process again.

With papers of the "Cyko" class it is essential that the negative should be free from all stain, or the time of printing will be unduly prolonged. The following method of intensification has been in use in a well-known North-Country studio for some considerable time,

and may be repeated up to the point of its action and to give an absolutely permanent result.

Make up to four solutions

		Water.
A. Potass. metabisulphate	150 grains	10 ozs.
B. Potass. bromide	400 grains	10 ozs.
C. Hydrochloric acid (pure)	20 drops	10 ozs.
D. Potass. metabisulphate	2 ozs.	10 ozs.

For use, take equal parts of A, B, and C. Bleach and immerse (after a brief rinse under the tap) in D solution until the yellow stain is completely destroyed. The negative is then re-developed in any non-staining developer without bromide, Azol or a para-midophenol mixture being especially suitable.

The method is equal to mercury in every way, with the additional advantages of being permanent, and that it is not necessary to eliminate all the hypo in the film previous to bleaching.

Buy pure chemicals, mix in the proper proportions, and use as directed above, and you cannot fail to get good results.—J. M.

Advertising by Airbrush.

AN American soldier, by trade a sign-writer, was recently making comparisons between this country and his own on questions of advertising, and, although we pointed out that the war had stopped experts here as well, he pointed out the difference between the stylish window tickets of City tailors, shaded in colours by the airbrush, with the old-fashioned printed silver letters on black in a studio showcase, and he could see no evidence that we had ever made use of striking designs and methods as are tried in America. He criticised photographers, and guessed that the majority had an artist and an airbrush on the premises, and yet they do not make use of the instrument at all for stencilling through and shading round a design, or even a little ground tint to letters calling attention to the studio's particular style, or inventing an attractive price-list panel for the window. American schools, such as the Detroit School of Lettering, use the airbrush largely for advertisement purposes, believing in colour and design as a means of arresting the eye.—BURLINGTON.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, January 27 to February 1.

PROJECTION—No. 2,158. Devices for use with optical apparatus for projecting pictures upon a screen. T. Burns, F. Palmer, and E. F. Scudder.

SHUTTERS.—No. 2,066. Devices for automatically releasing lens shutters of photographic apparatus. D. Friedmann.

AEROGRAPHS.—No. 2,046. Detachable colour cup for aerograph handpieces. R. Healey.

COLOURING.—No. 2,214. Colouring photographs, engravings, etc. S. T. T. James and J. MacDougall.

CINEMATOGRAPHY.—No. 2,512. Re-winder for cinematograph films. A. E. Jones and C. F. Lane.

CINEMATOGRAPHY.—No. 2,521. Cinematograph shutter. S. W. Pilling.

PROJECTION.—No. 2,501. Picture-projecting apparatus. I. Serrurier.

CINEMATOGRAPHY.—No. 2,027. Cinematograph films and manufacture thereof. J. E. Thornton.

COLOUR CINEMATOGRAPHY.—No. 2,028.—Cinematograph colour films. J. E. Thornton.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

W. B. DESIGNS, No. 365,675. Photographic chemicals. White Band Manufacturing Co., Ltd., 121, Selsdon Road, South Croydon, Surrey; manufacturing chemists. October 17, 1918.

METAGOL, No. 387,084. Photographic developers. Society of Chemical Industry in Basle (a share company organised under the laws of the Swiss Republic), 141-227, Klybeckstrasse, Basle, Switzerland; manufacturers and merchants. December 21, 1918. Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, FEBRUARY 22.

Edinburgh Photographic Society. Opening of Exhibition.
Huddersfield Naturalist and Photographic Society. Lantern Lecture: "Features of Yorkshire Bird Life." R. Fortune, F.Z.S.

MONDAY, FEBRUARY 24.

Bradford Photographic Society. "The Craven Highlands." F. Whitaker.
City of London and Cripplegate Photographic Society. "Snow Pictures." S. Coulthurst.
Dewsbury Photographic Society. Exhibition of Members' Prints. Private view.

TUESDAY, FEBRUARY 25.

Halifax Scientific Society (Photographic Section). "The Amateur Photographer" and "Photography" 1918 Prize Slides.
Leith Amateur Photographic Association. Social Meeting, with Whist.
Dennistown Amateur Photographic Association. Whist Drive.
Hackney Photographic Society. "By Train to the Land of the Midnight Sun." W. Sanderson, J.P.
Dewsbury Photographic Society. Exhibition open to the Public.
Chelsea Photographic Society. "A Loon in London." W. L. F. Wastell.
Manchester Amateur Photographic Society. "Views and Vagaries of an Inexpert Photographer on Photography and Art." J. W. Richards, M.A.

WEDNESDAY, FEBRUARY 26.

Croydon Camera Club. "The Potentialities of the Pinhole." B. J. Rose.
Ilford Photographic Society. "Another Chat on Pictorial Photography." S. Bridgen, F.R.P.S.
Photomicrographic Society. "Internal Structure of Metals." Dr. B. P. Haigh.

THURSDAY, FEBRUARY 27.

Liverpool Amateur Photographic Association. 1,000 miles Around Britain by River and Canal. Spenser-Jones, M.Sc.
Brighouse Photographic Society. Lectures.
Hampersmith (Hampshire House) Photographic Society. Members' Outing, Print and Lecture Competition.
Hull Photographic Society. "A Photographic Autobiography" and Y.P.U. Portfolio. W. M. Lyth.
Rodley and District Photographic Society. "Beginners' Pitfalls." Mr. Marston.
Chelsea Photographic Society. Dark Room.
Wimbledon Camera Club. "Some Experiences of a War Correspondent." H. C. Beckett.
Richmond Camera Club. "Monoliths." P. Varley.

FRIDAY, FEBRUARY 28.

Dennistown Amateur Photographic Associations. "Lantern Slides." R. Wallace.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, February 18, Mr. W. B. Ferguson, K.C., in the chair.

Mr. S. R. Williams delivered a lecture on "A New Process of Printing on Paper in Natural Colours," accompanied by a demonstration of certain parts of it. Briefly, Mr. Williams' process consists in making at one exposure with one lens a negative recording all three colour sensations in a series of bands as in the Joly colour screen plate. The banded colour screen of red, blue, and green lines is placed against the panchromatic plate in the well-known manner. Having made this negative, Mr. Williams places it in an enlarging lantern after having applied to it, in a special lantern stage, a key-plate consisting of parallel bands each double the width of those in the negative, separated by a space equal to the width of a single band in the negative. A fine link adjustment in the negative stage enables him to bring the lines of negative and key-plate into parallelism and then to move the key-plate so as to cut out the bands corresponding with any two of the colour sensations, and to project those of the third upon bromide paper on the easel. The difficulty in this operation of knowing which set of bands is that of a given colour sensation is removed by Mr. Williams by a series of distinctive marks made in the first instance on the colour screen plate and thus imprinted upon the negatives. The lecturer showed, by means of a large-scale model, how very easily this identification could be done. The key-plate in its special stage is thus twice moved through the width of a line and three bromide enlargements made representing the red, green, and blue-violet sensations. Here, as Mr. Williams pointed out, the process could be continued in many different ways. The bromide enlargements were amenable for the production of colour component prints by the Radex process: they could be employed as originals for pinatype or with some modification for the Sanger-Shepherd process. But his own choice was to make the three colour impressions by the bromoil process and to assemble them by a very simple method of transfer in registration. The bromoil print from the blue negative after bleaching was pigmented in yellow, and the impression transferred to drawing paper. The blue impression from the red

negative was first produced in pigment on the bromide print and then transferred to the yellow print by laying the second print down in registration and subjecting to pressure. The red impression from the green printing negative was transferred in like manner, and the whole process of making and assembling the three colour impressions could be done in about half an hour. Mr. Williams had found that ordinary drawing paper yielded colour prints, the shadows of which exhibited excessive opacity. He was seeking to remedy this defect by coating the paper with a mixture of celluloid varnish and oil containing a white pigment.

In some discussion which took place the lecturer explained that he registered the prints by means of a line made on the negative about midway along each side and thus impressed upon each print.

The absence of distinct blacks from the specimen prints having been noted, Mr. J. C. Warburg pointed out that such a production of black could not result in the process except from a spreading of the bands in each direction to the extent of their own width in making the enlargements.

Mr. Williams then proceeded to describe the means which he had used in making the colour screen plates himself. An immense amount of enthusiasm was created by the ingenuity with which the difficulties of inconstant light and irregularly working shutters were overcome. With a great fund of humour Mr. Williams entered upon a consideration of many practical devices, and on the proposition of the chairman the very heartiest thanks of the meeting were accorded to him.

CROYDON CAMERA CLUB.

In few societies do new members more rapidly become in spirit if not in fact old members, as is the case at Croydon. For instance, no sooner had Mr. H. S. Newcombe appeared on the scene than he was offered and undertook the duties of lanternist, no less sure with an alternating arc. Last week he gave a really practical paper on "Toning Bromide Prints," and passed round many prints toned in various baths, with the formulas neatly written on the back. These were mostly standard, but one print of a fine brown colour was obtained by just toning it blue in the usual way and then sulphiding.

In the discussion, which far exceeded the lecture in length, a member revived recollections of a demonstration on sulphide toning given many years back by the bright and festive John H. Avery. Alas! now no more. Mr. Harpur, with the innocent expression of a cherub, asked what would happen if only a rinse were given between fixing and bleaching. "The prints would seriously reduce in depth," said Mr. Avery. "Let us try," said the one without guile (who had previously made the experiment on the quiet), and a print was cut in half, one portion receiving the usual washing, the other a few seconds' rinse. No reduction occurred with the latter, the only difference being that it was slightly colder in tone. Rather a facer for John, who sought refuge in the adage that "one swallow does not make a summer."

Mr. Harpur agreed, and rightly, for all who manufacture photographic papers are aware that a procedure which may produce no untoward result at one time may be highly prejudicial at another, and accordingly issue instructions which are safe to follow under all ordinary conditions. A recent case in point may be of interest. The manufacturers of a certain printing paper were asked by a user abroad whether a certain procedure could be employed instead of the one recommended. The answer was in the negative. They were subsequently informed that the alternative had been tried, notwithstanding, and with complete success. Leaving out of the question of the possibility of a difference of opinion on the degree of success obtained, the explanation of the mystery is simple. The user being in a far-distant land was necessarily working with old paper, whose age enabled it to withstand a treatment which would have been fatal with fresh paper.

Some time ago the present august president, Mr. J. Keane, expressed a pious belief that he had secured finer sulphide tones by conducting the manipulations in red light. Mr. H. King, a professional never above considering a new idea, said he had tried this, the only difference discoverable being the fracture of a 20 oz. measure, which would not have occurred in white light. Many might be interested to hear that very fine red-chalk tones could be obtained with sulphided prints. After sulphiding, the prints are

washed for 30 minutes in 12 changes of water, and further toned in:—

Hypo	2½ oz.
Soda carbonate	30 grains.
Gold chloride	5 grains.
Water	10 oz.

and then well washed. Prints must not be dried previous to the gold toning.

Mr. S. J. Rose, who all were glad to welcome on his return from France, gave some highly interesting details of the heavy photographic rush work between intervals of "nothing doing." One observation of his came as a surprise; he stated in his section the use of amidal was forbidden for developing bromide enlargements, owing to its injurious action on the hands, metol-hydroquinone being exclusively employed; rather a reversal of usual ideas. Mr. V. Jobling said, having some weak lantern-slides he bleached them by the bichromate method, and added a mere trace (amount of tinging to a stirring red to be precise, or the reverse) of the sulphide bath to the re-developer. Added contrast, and a rich warm-black resulted.

In reference to uranium toning, Mr. E. A. Salt said that all bromide prints so toned by him in the past were now wrecks. On the other hand, platinotypes toned with uranium fifteen years ago and over showed not the slightest change in colour. Very beautiful warm-blacks to foxy brown-reds were possible. Mr. J. M. Sellers said uranium toning now had rather a bad name, but once was the rage. He had a uranium toned print at home thirty years old, and only recently had the first signs of the familiar metallic sheen appeared. This had been completely removed by india-rubber, as first suggested by their member, Mr. C. Welborne Piper. Personally, he rarely sulphided bromide prints as he indulged in "scratch work," and this revealed the underlying black. He preferred the old hypo-alum bath to more modern methods. Mr. A. F. Catharine, without visible effort, concurred. In his hands hypo-alum afforded superior tones.

A most hearty vote of thanks was accorded Mr. Newcombe, who is to be congratulated on an excellent lecture and a successful "first appearance."

EDINBURGH SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

The fifth meeting of the season took place on February 10, to which all the photographers of Edinburgh and district had been invited. There was a large attendance. Mr. Young was in the chair.

A letter was read from the Secretary of the Edinburgh Photographic Society intimating that the Council were desirous of inviting the Scottish National Salon to Edinburgh in 1920, and asking if the Edinburgh Society of Professional Photographers would be willing to participate. After some discussion it was felt that as the Professional Society had in view the holding of an exhibition of their own, and in the absence of any detailed information regarding the Salon, this matter should not be considered meantime, and the Secretary was instructed to write to the Edinburgh Photographic Society to this effect.

A letter from Messrs. Olymns Davis was read, in which they requested information regarding the constitution of the Society. The Chairman read a letter from the Secretary of the Edinburgh College of Art intimating that the proposed retouching class scheme had not been passed by the board, and suggesting that photographers might perform their own tuition. Mr. Young then read the text of a memorial which he had drawn up, and which it was proposed should be signed by the photographers of the city and submitted to the board of the College of Art. The memorial, among other things, pointed out the impossibility of photographers instructing their assistants personally, and referred to the number of classes of various kinds included in the syllabus of the College, and which were no less removed from "art" than retouching. The memorial was unanimously accepted, and Mr. Campbell Harper expressed the Society's indebtedness to Mr. Young for the trouble he had taken in this matter.

The meeting then discussed the question of a minimum price for postcards. Mr. Campbell Harper suggested that, in view of the war price-cutting, a number of photographers should agree not to go below a certain price. People would go long distances to secure certain photographers' work, but not to secure lower prices. Mr.

Mackay suggested that a meeting of postcard photographers might be held to discuss the matter fully. A number of different prices were mentioned as being charged by various firms, and it was ultimately agreed, on the motion of the Chairman, that a recommendation be passed that no photographer should charge less than 6s. per dozen for postcards. This it was decided to communicate to all photographers in the district.

The holiday closing scheme was then discussed. It was thought that this year photographers should close during different periods, so that there would always be some studios available for the public. A minimum period of one week was proposed by Mr. Barrie and seconded by Mr. Campbell Harper; while Mr. Ferguson proposed ten days, as last year. Mr. Johnston proposed that these two motions should be allowed to lie for a month, during which time the Secretary would place them before the remaining photographers of Edinburgh and invite opinions.

It was intimated that a criticism of members' prints by a well-known artist would take place at the March meeting. Those present then signed the memorial, and the meeting closed.

Correspondence.

KINEMATOGRAPH.

To the Editors.

Gentlemen.—I think Mr. A. Lockett is wrong. Cinematograph was first a trade-name for Lumière's in 1891; bioscope an English name in 1894. Kinema was first used for an English patent in the 'sixties or 'seventies; since that time the English Patent Office classifies under "K." The oldest trade journal also goes under the name "Kinematographic Journal." My English standard dictionary, 1902, also says "K," and does not mention the Cino (which is pronounced sino, not kino)

The first kino consisted of a pack of cards, on which the successive movements of an object were illustrated by hand, when slowly released, as in the modern Mutoscope or Kinora, the kinematographic effect was produced.

The name is, therefore, typically English, and not of Germanic origin, as suggested; nor is Lockett, because it is written with "ck," and "ck" is looked upon as typically Germanic. KINO.

THE MERCURY-VAPOUR LIGHT.

To the Editors.

Gentlemen.—Referring to the correspondence on pink diffusers for the mercury-vapour light, I should like to say that I found a great reduction of the greenish tint without any appreciable lengthening of exposure. The colour used was quite a full rose pink; a paler colour did not seem much good.—Yours, &c.,
C. H.
Birmingham.

To the Editors.

Gentlemen.—Referring to the communication by Mr. Stanley Beaufort, which appeared in your issue of February 14, I may say that I used the mercury-vapour system exclusively about six years ago. The unpleasant appearance which the light imparted was certainly objectionable, and every expedient was tried to get rid of the drawback.

The pink curtain proved of no visible use. The rhodamine-dyed reflectors, referred to by Mr. Beaufort, were more satisfactory, but we found the colour of the reflectors faded; thus their effect was gradually lost.

The most permanent and satisfactory results were achieved by the use of a few ordinary 50 c.p. incandescent electric bulbs, placed at intervals near the mercury tubes.

It may be interesting to mention that this light, on the stand, as originally sold, did not meet with my ideas of good lighting, but, by discarding the stand and reflectors and making a radical rearrange-

ment of the disposition of the tubes, highly successful work resulted, and I recall with pleasure the use of this modified system of mercury-vapour studio lighting.—Yours faithfully,
J. SPENCER ADAMSON.

SHORTER HOURS IN THE DARK-ROOM.

To the Editors.

Gentlemen,—I wish to state the case for dark-room assistants as briefly as possible. Dark-room work, at the best of times, is not by any means the most congenial part of photographic work, especially when one is at it for nine or ten hours a day in small stuffy, partly ventilated rooms, as many of them are, as I know too well. The hours of such kind of labour are in many cases far too long. Too much of it, especially in the dingy holes which serve as dark-rooms in many parts of the country, is always detrimental to health. Since leaving the army I have been on my own in photographic work, and practically all our printing is done in matt P.O.P., which is, I consider, very much more satisfactory and gives more artistic pictures than prints on bronzé paper. In pre-war days the terrible monotony of dark-room work was very trying, so I plead to all professional photographers throughout the country to consider the question regarding their dark-room assistants, and to reduce the hours to a maximum of seven hours for five days in the week and three and a-half or four for the early closing day. Seven hours a day is plenty long enough for such trying work, and if no time is wasted a considerable quantity of work can be turned out in the course of a day.

I would like to hear further on the matter from photographic employers and employees.—I am, gentlemen, very truly yours,
"Moss Bank" Studio,
C. F. WATKINS.
Etchingham, Sussex.

THE HYDROQUINONE-RODINAL DEVELOPER.

To the Editors.

Gentlemen,—Reference is made in your "Answers to Correspondents" of last week (page 79) to the hydroquinone-rodinal developer, a little-known combination which did not merit the approval of many workers. "G. D." is informed that there was no published formulae for the combination "as far as we know." As a matter of fact some formulae were published about sixteen years ago, but as the "combining" fever was then at its height, and so many combinations of the many different developers appeared—many of them of little consequence and even less use—the less important of them may have escaped your notice, notebook, index, and memory.

Of the many combinations which have been advocated that of hydroquinone and rodinal appears to have attracted the least attention, at any rate it never earned the approbation of any plate-maker or developer-maker. Pyro-metol and metol-hydroquinone are to-day the sole relics of the once-popular craze of mixing developing agents, although pyro-glycin, adurol-metol, eikonogen-hydroquinone, and metol-glycin tried hard for a place, and certainly managed to find their way into instruction sheets and handbooks—a thing hydroquinone-rodinal never did to my knowledge. The "published" hydroquinone-rodinal formulae I have in my large collection are from American and German periodicals and the English "Photographic News."

A formula which came from a German source in 1903 stands as follows:—

A.	Soda sulphite	1 oz.
	Hydroquinone	120 gr.
	Citric acid	5 gr.
	Potassium bromide	10 gr.
	Water to	20 oz.
B.	Potassium carbonate	2 oz.
	Water	20 oz.
	Rodinal	1 oz.

To make up a working developer for soft or "portrait" negatives take equal parts of A, B, and water; for strong negatives use equal parts of A and B and no added water. By varying the amounts of the A (hydroquinone) and B (rodinal) solutions one could, the originator of the formula told us, obtain hard, soft, or any other kind of negatives. This was quite all right in theory because of the well-known density- and detail-giving powers of the hydroquinone and rodinal solutions respectively, but in practice the ringing of the changes did not produce with certainty the wonderful results one was led to expect. A combination which came to us

from America in 1905, and one "fathered" by one of the photographic colleges there, is of a different type:—

A. Hydroquinone	40 gr.
Soda sulphite	200 gr.
Rodinal	16 drops.
Water	4½ oz.
B. Potassium carbonate	60 gr.
Water	2 oz.

This, we are told, is really a one-solution developer, because the A solution will work by itself, it containing the two agents. The addition of a few drops of the B solution to each ounce of the normal (A) developer quickens development very considerably, and more or less of B is recommended for hand camera and under-exposures. Indeed the "inventor" of the combination went so far as to advise equal parts of A and B for focal-plane exposures.

In conclusion, I may say that I am sending you the formulae because they have been asked for, and you may deem it advisable to record them in your pages. I am not sending them because I consider them to be superior to any of the standard hydroquinone-metol formulae, although some workers have stated them to be so. After making some experiments at the time of the craze for combining developers I came to the conclusion that if rodinal was to be called upon to assist hydroquinone in the work of developing a negative the best plan was to develop partly—for density—with a normal hydroquinone solution, then wash and finish with weak rodinal for details, or to get out the details first with rodinal, wash, and then go for density with a normal hydroquinone developer. But, after all, it is doubtful if the orthodox metol-hydroquinone combination can at the moment be beaten, although a hydroquinone and rodinal or azol mixture has possibilities, and might well claim the attention of experts in these days of "reconstruction."—
Yours faithfully,
GOURNAY WILSON

THE ASSISTANT QUESTION

To the Editors.

Gentlemen,—I have followed with a good deal of interest the correspondence which has been toward with regard to the assistant question, and as an old exponent of the question—I wrote you several letters on the subject some five or six years ago—I should like to record my thanks to your many able correspondents.

At the same time, I would like to ask what is the position of assistants who are not yet released from the Army?

For myself, I am comfortably off just now, but I do not aspire to spend the rest of my life in the service of the Army, so that, if we are to be taken into consideration in getting out the details of the scheme, I should be glad of information.

I need only add that I have had chats with many other assistants and employers both in the infantry and the R.A.F., and all are agreed that something ought to be done; but, of course, the old apathy of our class has to be taken into consideration, and, so far as I am able to help while in the Army, I am entirely at the service of Mr. Adams and yourselves.

The scheme of exams. which is seriously advocated now is a jolly good idea, and ought to meet with the approval of all qualified men, and in my present capacity of lecturer on photography under the Army Education Scheme I could, perhaps, do something to bring about such exams. for men in the Northern Command; in any case, I may be able to help; if so, and in whatever way desired, please let me know, and I'm on the job. If men could go out of the Army with a certificate of ability it would no doubt help on the cause greatly.

In conclusion, Gentlemen, I wish the good old "Journal" every success in its honest endeavours on our behalf, and a long and prosperous life. It seems to forge along, despite all difficulties.—Yours faithfully,
ARTH. J. BACOX, Sergt
(Late Cadet, R.A.F.)

No. 3 Section, Humber Garrison, Winestead Hall, near Hull.
February 9, 1919.

To the Editors.

Gentlemen,—If I may add to my previous letter I should wish to point out to Mr. Houghton where I am not in accord with his suggestions.

In the first instance I do not consider it to be a duty of the P.P.A. to provide or assist in providing training facilities for

assistants. That, surely, is an imposition, and opens out too many possibilities for abuse. An employer could take any number of apprentices and the P.P.A. would do the rest. On this point I contend that an employer should train his own apprentices. If he is not competent to do so or neglects that duty, then it should become a matter for a court of law. That point must not be forgotten even if your correspondent is dealing with the older and recognised assistant and his needs. His needs are training and greater efficiency. The responsibility for that lies with the man who should have trained him—the man who encourages inefficiency by employing him, and the man himself for not demanding greater knowledge. But how do we arrive at this fact that assistants are lacking? At present it is a mere hazard of individual deductions. And having arrived at such a conclusion by these unsatisfactory means it is a simple matter to hand over the work of reconstruction to the only body in existence. It is a suggestion which would not stand practical application, and I do not think the P.P.A. will adopt it. I am convinced that if the P.P.A. will formally draft a standard of attainment—a high one and stick to it—that body will have done something far more practical. To do that and to supply information, as stated in my previous letter, is all that is necessary and desirable. As an assistant I do not look to the P.P.A. to complete my training. If a standard is set and I am found lacking, then I can "swat" and become efficient, as men do in other professions. But I do claim the right to know what I am supposed to possess in the matter of skill. Obviously, until that information is forthcoming any assistant doing responsible work can claim to be a qualified assistant.

Dealing with the question of certificates I consider references for daily work given on official forms based on the fixed standard of attainment, would be more practical for ordinary use. A short examination is not a criterion of a man's capabilities. If at any time after becoming a recognised skilled worker an assistant wishes to qualify for a manager or a head of department, examinations could be arranged and certificates given. Those examinations should be thorough, and anyone holding such a certificate should be recognised as possessing a very high degree of knowledge and skill.

To make membership of the P.P.A. conditional would answer no purpose at all. Assistants are not anxious to become certificated members of the P.P.A. Assistants I believe are quite as anxious to get to the bottom of all things photographic as are employers. And it can only be possible to come to a satisfactory solution of the whole matter by getting to know what each other is thinking and going to do about it.

Primarily we have to consider the status of photography as a profession. That subject immediately unfolds into two aspects; the employer's and the assistant's. Those two aspects give rise to two solutions; antagonism or fusion. I plump for the latter; hence I suggest that the P.P.A. be open to all photographers.

This point is I believe the main issue in this correspondence. The challenge of inefficiency has crept in. I do not deny its truth. But it is a direct challenge to assistants, who I hope will take it up. And I hope, too, employers mean that they do wish for more efficient assistants.

Regarding the whole matter as a serious proposition, I think the amalgamation of ideas in one association is most important. For whatever the claims of employer or assistant may be, they are all useless, unless by united effort photography as a profession is lifted high and held there.—Yours truly,
ROWLAND SAMMES

Regate

THE LATE LIEUTENANT C. F. LAN DAVIS.—We notice in the brief particulars of the will of the late Lieutenant Cyril Frederick Lan-Davis, which have been published in the daily papers, that the estate of the deceased gentleman amounted to over £18,000. Of this £5,000 was left in trust for pensions to persons now or formerly in the employment of Messrs. J. H. Dallmeyer, Ltd., of which Mr. Lan-Davis was a director.

THE PHOTO MICROGRAPHIC SOCIETY.—The next ordinary meeting will be held on Wednesday, February 26, at 7 p.m., at King's College Bacteriological Laboratories, 62, Chandos Street, W.C., when Dr. R. P. Haigh will lecture on "The Internal Structure of Metals." Visitors are invited, and cards of invitation may be obtained on application to the Hon. Secretary, J. G. Bradbury, 1, Hogarth Hill, Finchley Road, Hendon, London, N.W.4.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller price will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed or reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

E. A.—The Manchester College of Technology, Sackville Street, Manchester.

J. S.—The Order in regard to the opening of new businesses has not, so far as we know, yet been revoked, and although, perhaps, not always strictly enforced, it would be as well for you to make application for a permit to the Director of National Service, South Road, Nottingham.

F. W.—We have never heard of carbon printing being done by acetylene light, and we should say that the number of lamps required would produce an amount of heat which would make printing impossible. The only artificial lights, in our experience, for carbon printing are mercury-vapour and the enclosed arc.

S. B.—The glass should, if possible, be at least 18 inches wide and on as long strips as possible; if you can get it in three pieces for the 8 ft. it will do very well. Rolled plate is the strongest and best. The top light should come about half-way up the roof if you want to do groups; 6 ft. will do for single figures. We assume the background will be at the door end, for at the other end the window is awkwardly placed.

G. T.—The two lenses are evidently both $f/3$. The marking with f values is comparatively modern, and the older lenses were marked 1, 2, 3, 4, etc., with no reference to the focal value. Therefore we should say the C. and G. lens was dear compared with the Ross. You do not give the aperture of the 10 in. Ross lens at £5. If anything near $f/4$ it should be a bargain. In portrait lenses Ross and Dallmeyer are about equal in value for similar sizes.

A. G.—Any coal-tar dye "soluble in spirit" would answer your purpose, but, so far as we know, nothing has been done in ready-made mixtures to match wood. Moreover, many of the dyes will not stand exposure to strong light. We have found Stephen's stains the most satisfactory for the purpose, and if you are careful they should not warp the frames. If you want to try the dyes, write to Messrs. Lindsay and Co., chemists, Leather Lane, London, E.C.

G. P.—For large heads, ten or twelve inches is still rather a short focal length: fourteen or sixteen inches is better. An R.R. is quite a suitable type of lens where, as in your circumstances, there is plenty of light. The Instantograph camera is one of a very light build, and in the half-plate size certainly not suitable for carrying a lens of even 10 or 12 inches focus. If we were you, we should buy an old pattern, long-focus camera, such as you can get for a pound or two from a second-hand dealer.

G. B.—A reliable firm for such of the photographs as are likely to be taken by the newspapers is the Press Photographic Agency, 170, Fleet Street, E.C. As regards the photographs of children and other subjects which are not of topical interest, the most likely purchasers are the publishers of postcards, of whom the largest buyer is the Rotary Photographic Company, West Drayton, Middlesex. But they buy only, as a rule in sets of six, and

therefore, in order to make it possible for them to offer, you would need to arrange the subjects on this basis. Perhaps the Press Photographic Agency would be able to look after this business also for you among firms who issue calendars and the like.

J. H.—We are quite in accordance with your idea that better quality may be obtained by using reflected light in enlarging than by using direct light through a condenser. The only difficulty is the length of exposure when working from dense negatives, and, in fact, the almost impossibility of getting through the high-lights of a very yellow one. The Boardman pattern is quite a typical one, and should answer well for average negatives. At the same time, we think you might do well to inquire as to the new Cooper Hewitt Gridiron lamp. This is very much used in the United States, and some of the large firms here are trying it. Address your inquiry to the Westinghouse Cooper Hewitt Company, 80, York Road, King's Cross, N. With regard to general fittings, we can only think of one piece of advice which may be useful, and that is to have plenty of sink room. You can easily cover it when not wanted, and when you have a big job it is there. Of course, you will instal your copying camera on a proper table with runners, an adjustable easel and lights on both sides; half-watts will do splendidly for these. For developing light use two thicknesses of golden fabric and have plenty of light area.

FORTHCOMING EXHIBITIONS.

February 10 to 22.—Glasgow and West of Scotland Amateur Photographic Association Inter-Club Exhibition. Secretary, Gilbert S. McVean, 125, West Regent Street, Glasgow.

February 20 to 22.—Leicester and Leicestershire Photographic Society. Secretary, H. C. Cross, 80, Harrow Road, Leicester.

February 22 to March 8.—Edinburgh Photographic Society. Entries close February 13. Secretary, George Massie, 10, Hart Street, Edinburgh.

April 17 to May 22.—Hammersmith Hampshire House Photographic Society Annual Exhibition. Two open classes. Entries close March 13. Joint secretaries, J. G. Abrahams, 41, Hamilton Terrace, London, N.W.8; A. H. Page, 12, Lime Grove, London, W.12.

EASTMAN KODAK COMPANY.—The directors have declared the following extra dividends:— $2\frac{1}{2}$ per cent. upon the common stock, payable on April 1 to stockholders of record on February 28; 5 per cent. upon the common stock, payable on May 1 to stockholders of record on March 31. The ordinary quarterly dividends of $2\frac{1}{2}$ per cent. upon the outstanding common stock, and $1\frac{1}{2}$ per cent. upon the outstanding preferred stock will be paid as usual on April 1 to stockholders of record on February 28.

SUMMARY

The various considerations which are of the utmost importance in choosing a site for the studio are the subject of the article this week by "Practicus." It is shown, by a number of instances, that difficulties in the site may be overcome and without great sacrifice in the efficiency of the studio. (P. 95.)

An article in the "American Annual of Photography" by Mr. J. I. Crabtree, of the Eastman Research Laboratory, deals in a very comprehensive way with the many causes of chemical fog. The effect of minute impurities in the developing solution and of the manner of compounding the developer are particularly worthy of notice, since they are the least likely to be detected. (P. 97.)

In a leading article, we point out the commercial value of an equipment of lenses sufficiently varied for exceptional occasions. The usefulness of a lens of extremely wide angle and, on the other hand, of one of the telephoto type is perhaps not so widely realised by the professional as by the amateur. (P. 94.)

Some hints on the obtaining of expression in the sitter at the time of exposure are contained in some brief notes by Mr. W. E. Debenham. (P. 100.)

The report of the Professional Photographers' Association is presented at the forthcoming annual meeting records a membership last year of 915, and deals with other matters which have engaged the attention of the Association. (P. 100.)

A considerable number of exhibits related to the photographic trade are to be found in the British Industries Fair now being held in the Pennington Street premises of the London Dock and remaining open until March 7 next. (P. 101.)

Some practical hints on the celluloid facing of prints are contained in an "Assistants' Note" on page 102.

In the design of field cameras, makers show a tendency to cut things too fine in the way of making the bellows large enough to avoid cut-off when the lens front is placed in an exceptional position. (P. 94.)

The making of a stock solution of a single chemical is more conveniently done, and the solution is likewise more convenient in use, if the strength of the solution be appreciably less than saturated. We instance the usefulness of this method in a paragraph on page 93.

The commercial photography of flowers, for which there is a demand among growers and seed firms, is largely a question of recognising the "points" which a bloom possesses and giving due emphasis to these latter in the photograph. (P. 94.)

EX-CATHEDRA

Phase and Change.

While much is being talked of reconstruction on the grand scale, in the comparatively small field of photography we see things changing as the inevitable result of the circumstances of the time. The balance between the supply of and demand for labour—if that can be called a balance which a few months ago showed the latter to be immensely in excess of the former—has been disturbed, and signs are plainly discernible of a reversion to the pre-war conditions under which the supply, or, at any rate, the publicly offered supply, was greater than the demand. It is easy to understand that the progress of demobilisation in conjunction with the new labour which has been recruited during the war should tend towards this condition in the ranks of photographic assistants. And the same thing is observable in respect to the firms or individuals who cater for photographers' trade work. Such who have come into existence during the war now find themselves in competition with the demobilised ones who formerly had their established circle of customers, and are now taking active steps to recover their business. The circumstance provides a caution to those who may be thinking of purchasing a war-created business of this kind. A connection is difficultly held, and from several motives customers will be likely to return to those who previously had their patronage. The difficulties of supply, and, in many cases, the lower quality of work during the war period are factors which will operate in the direction of restoring custom to those who previously had it, and for this reason a business which is no more than two or three years old becomes a somewhat speculative proposition.

Strong v. Saturated Solutions.

The keeping of certain chemicals in saturated solutions is a recommendation which comes from the old days of photography, when workers had a nodding acquaintance with practical chemical operations. At the present time, when such knowledge is the possession of a very small minority, the practice may lead to a degree of error which may not be suspected by the individual worker. Few will take the trouble to test the temperature of a saturated solution or to make certain that it is saturated at that temperature. And even if that is done, an awkward calculation is necessary in order to discover the quantity of solid chemical which a given volume of the solution represents. On these accounts it is a much better plan, we think, to sacrifice a measure of the concentration afforded by a saturated solution and to obtain in exchange the certainty of constant strength and the convenience of translating from solution to solid. To put this idea into a concrete shape, a saturated solution of hypo is one which varies greatly in strength according to the temperature, and at any given tempera-

ture represents per unit volume an odd weight of the chemical. A much more satisfactory and convenient plan of keeping hypo in concentrated solution is to dissolve the crystals in water and make up to a volume corresponding with twice the weight—for example, 1 lb. of hypo dissolved in water to form a total bulk of 32 ozs. One ounce of hypo is then contained in every two ounces of the solution and the making up of fixing baths of any required strength becomes the simplest of arithmetical calculations. The same plan may be adopted for less soluble substances, choosing a ratio of 1:3 or 1:4 in place of the 1:2 which is possible only for such extremely soluble substances as hypo, potassium carbonate, and a few others.

* * *

Commercial Flower Photography One of the most difficult branches of commercial photography is the portrayal of flowers, fruit, or vegetables for catalogue illustration, yet it is work that is frequently in demand. A good knowledge of florists, flowers and horticulture generally will go far to helping the operator in emphasising just those points that the grower or advertiser wishes to put forward to his public. Perhaps our meaning may be the more plain if we give a simple illustration, taking the case of that popular flower the sweet pea, one, which it may be added is constantly being improved by various growers who are rapidly coming to see that one of the most direct, simple and effective methods of advertising the value of their new varieties and bringing their good points before flower-loving connoisseurs is a good photograph of a perfect bloom. Among the points looked for in the perfect sweet pea are the number of flowers that can be grown upon a single stem, their spacing upon the stalk, the length of the latter, a most important point, the size of the individual blossoms, and in connection with this an absence of what is technically termed "coarseness," and lastly the colour of the flowers. If a photograph of a perfect bloom selected at some trouble by a fastidious grower is to be a success then it will have to be something more than an ordinary hit or miss photograph of the bloom, and it will need to be arranged so that the points of the flower are shown to their best advantage. Thus the adjustment of the bloom in its holder or vase is important, likewise the position from which the picture is taken, and the rendering of its texture. In the case of vases of flowers, much the same rules will have to be followed as in the case of single specimens: nothing in the way of a "bunchy" arrangement is to be permitted. Backgrounds are best made of large sheets of mounting card of various colours, and these may also be employed for growing plants out of doors in isolating the subject from its background. Upon the technical side little need be said. An ordinary field outfit having long extension and a good lens of fairly long focus is as good an equipment as can be desired, since, except in the case of flowers growing outside, speed is not of importance. Of course, panchromatic plates and a set of screens are to be regarded as absolutely essential in order to secure correct colour rendering. A thin negative having abundant detail is best, those obtained by the tank method being highly satisfactory. It is becoming realised that a photograph is more satisfactory than one of the best drawings; colour photography is likely to popularise this branch still further, and commercial photographers should take full advantage of the demand.

* * *

Field Camera Bellows. The modern field camera is looked upon, and justifiably so, as an instrument of precision, and in many ways it is difficult to see how the standard design can be improved. There is one point, however, that is frequently overlooked by designers, and that is the importance of fitting their instruments with

bellows of sufficient width. Not only do wide bellows avoid trouble due to reflected light from their inner folds, but also it is next to impossible when using wide angle lenses of short focus to avoid some "cut off" of the image on the plate by the edges of the bellows, particularly when these are made to give a long extension. This form of trouble is the more likely to be met with in the conical bellows form than when the instrument has parallel bellows. For the latter type we must confess we have a preference, but even when conical bellows are in use there is no reason why the maker should not fit them of sufficient size to prevent the trouble referred to. Some cameras that we have seen leave much to be desired in the size of their bellows, and we can call to mind one of our own instruments that could never be used with success for wide angle work for this reason. Such a fault in an otherwise excellent design is spoiling the ship for ha'porth o' tar. When the bellows are made for long extension there is often a tendency for them to "cut off" part of the image when used at a shorter extension, and for this a loop of elastic is sometimes fitted to the top of the bellows in order to draw away the extra folds from the line of rays thrown by the lens. We have found in practice that this plan is not very satisfactory, and have supplemented the loop with two more, one at each side, which are attached to the nuts holding the swing front. In this way the extraneous folds are drawn entirely out of the way. When old bellows are inclined to sag in the middle at a long extension, a couple of loops of extra length attached in the same way will go far to overcome the trouble.

LENSES FOR ODD JOBS.

Most professional photographers would be surprised if they were told that in the matter of lens equipment they were far behind many enthusiastic amateurs, but we believe that we are correct in making this assertion. The fact is, that the professional is rather apt to put all his eggs into one basket, or, in other words, to invest in a few first-rate lenses and to consider that he has done all that is needed. He selects lenses for the size of the plate he generally works, and, so far as it goes, this is quite correct; but he seldom has anything to fall back upon for any job which may require one of a different focal length. It is remarkable that this is more likely to be the case with the photographer of to-day than it was a quarter of a century ago. Then it was not uncommon to find an equipment of a complete set of portable symmetricals, twelve in number, ranging from three to twenty-one inches in focal length, the first ten fitting the same flange and in many cases having the lens cells interchangeable, so that even a variation of half an inch in focal length could be obtained. There were also "casket" sets, usually not of the finest optical quality, but good enough when used with small apertures, which gave an even greater range at a very reasonable cost.

The portrait man does not, of course, need such a variety of tools, but the man who is willing to take on any class of work frequently finds that he cannot do exactly as he wishes, and, what is more important, what his client wishes, because of his imperfect equipment. This state of things can easily be remedied at quite a small cost if it be borne in mind that a comparatively poor lens works nearly as well as an expensive one if it be possible to use a small aperture. Another point to be remembered is that with modern enlarging methods at our command it is not always necessary to limit ourselves to one particular size of plate, since, if we can get our subjects, it is easy to make prints of a larger or smaller size as may be required.

Let us take a few examples of possible orders and how they may be executed, or, to be more precise, how such

orders have been executed. An extremely wide angle view of a street scene was required to show the disadvantages which would result to a shopkeeper if a railway viaduct were put near his premises. No orthodox lens would give the necessary view angle, but by using a four-inch lens which happened to be at hand, a negative was made upon a whole plate, which did just what was wanted: it gave the width of the picture well defined, and when the top corners were blocked out a 15 × 12 enlargement was made which did good service in court. Now, how many photographers have a decent four-inch wide angle lens in stock? Yet it is not an expensive tool, and if not paid for by the one job, its possession helps to build up a reputation for efficiency which leads to future orders. Such a lens is not only useful for outdoor work, but for enlarging when only a moderate length of bellows is available. If it be necessary to take a small head out of a group, a considerable degree of enlargement can be obtained directly instead of having to resort to a second enlarging process. Conversely, such a small lens is of great value for making reductions with the enlarging lantern. If a copy, say, an inch by three-quarters, or less, has to be made from a cabinet negative it is easy to do so.

Going to the other end of the scale it is a rare thing to find a telephoto lens in the hands of the ordinary photographer; yet it is a most useful instrument for many purposes besides taking distant views. We remember some years ago, when the original Adon was introduced, being told by a large firm who specialised in catalogue work that they had been recommended by an amateur to try a telephoto lens for the photography of small articles, with the result that they had greatly improved the perspective in every case to the satisfaction of their customers and their own profit.

While comparatively cheap lenses of the old rectilinear construction are capable of doing much useful work, we should not recommend their purchase if funds permit of

more modern instruments being obtained, for when a lens is being used for copying or in the enlarging lantern at an extension which is many times its focal length, a large aperture is of great advantage, the difference in luminosity between one having an initial aperture of $f/6$ and $f/16$ being very noticeable, and if such lenses are of the "convertible" type, giving two or three focal lengths, their utility will be increased. Still, before purchasing new lenses it is as well to take stock of what lenses are on hand, and to make a note of their focal lengths. If duplicates of any one size are found one should be sold or exchanged, so as to secure further variety.

It may be found that although suitable lenses are available, there is no means of using them upon large cameras or enlarging lanterns, and it is therefore advisable to have them adapted to the flanges already upon such cameras. This can be done at the cost of a very few shillings, and in the case of modern instruments it is not necessary to part with the lens or large flange, as these will be of standard size, and it will only be necessary to mention the diameter. For a makeshift, a very good plan is to cut a hole in a piece of card so that the lens thread will just go through, securing it by screwing on the flange at the back, the card being attached to the camera front by means of four drawing pins.

Supplementary lenses of the Planiscope type will often prove useful, to shorten the focal length of lenses which will not give the desired angle or magnification, but it will usually be found necessary to work at a very small aperture when these are used, as the corrections of the original lens are upset. However, for this class of work speed is usually not necessary. A makeshift Planiscope may be made by attaching an ordinary small single lens, such as the front of a small portrait lens or one of the combinations of a rapid rectilinear, by means of a cardboard ring. This sound rather crude, but we have known it to be done with success.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communi- cate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
The Camera and the Lens (Jan. 10).
Managing the Sitter (Jan. 24).
Backgrounds (Jan. 24).

Studio Exposures (Jan. 31).
Artificial Lighting (Feb. 7).
Printing Processes for Portraiture (Feb. 14).
Studio Accessories and Furniture (Feb. 21).

THE SURROUNDINGS OF THE STUDIO.

Some writers on lighting in the studio have treated the matter as if all studios were alike, and that a set of rules, which should ensure any desired result if they were followed, could be evolved. There could be no greater error, for hardly any two studios are exactly alike; in fact, so great is the difference that an operator who has created quite a reputation for artistic work in one will fail dismally in another. It has been my luck to work in many oddly constructed places, but I have hardly found one where, with a little study and perseverance, decent results could not be obtained, the principal difference being not so much in the appearance of the negatives as in the length of exposure necessary to obtain them. This, I hope, will be of some comfort to those who have found an otherwise eligible position for a studio,

but are doubtful as to its possibilities in the way of lighting.

There are two main points to be considered, one being the orientation of the building, or its relation to the cardinal points of the compass, and consequently to the sun, and the other the presence of outside obstructions in the shape of walls, trees, or other objects. Regarding the first, I think that too much stress has been laid upon the necessity for a northern aspect for the glass side; in fact, I have known cases where a photographer has gone to great trouble and expense to secure this or even to reject a position where it could not be obtained. For instance, where it has been a choice between securing a good working length with an eastern aspect or too short a studio for good work, the latter has been chosen, simply from fear of not being able to control

the light in the former position. This idea dates back to wet-collodion days, when it was considered essential to have a large amount of open light, and has been handed down from one writer to another, although we must not forget that even in those early days Mr. Valentine Blanchard, whose artistic ability has never been questioned, proved that the finest possible work could be done all the year round in a studio facing due south. I frequently work in a studio with a full western aspect, and find no difficulty in doing so, although I must confess that I should like it much better if it were a northern one. The reason for this is, of course, that in the latter one can get the same effect all day without altering the blinds, while in the former modifications are necessary as the light works round.

To make the best of a studio so situated that the sun shines upon the glass, it is necessary to be able to cover the whole of the light either with dark or white blinds or curtains as may be needed, but when I say white blinds I do not mean pea-soup colour, which is the normal tint in many studios. These intercept so much light that they are useless as diffusers, which is their real mission. Mr. Blanchard screened his sunlit roof and side with light frames, upon which tissue paper was stretched; but I prefer my favourite white mainsook festoon curtains, as they may be easily pushed aside when not required, and are, moreover, easily washed when soiled. I have worked in a studio glazed with ground glass, but found that there was too much glare, and when white blinds were used in addition the exposures were too long. It is almost needless to say that in a sunlit studio there must be no bare glass, the white blinds being the source of light, when they act much in the same way as if a sky covered with white clouds were seen through clear glass. The simile is, perhaps, not quite good, but that is as nearly as I can put it. In such a studio the inside walls must be rather dark or flatness will result, and the area of white blind used must be no larger than is necessary. If we consider the ease with which good results can be obtained with a single enclosed arc lamp we shall see that a very large area of light is not necessary.

The second point, that of outside obstructions, is a more difficult one, and every individual case must be dealt with as a special problem. During the past few weeks I have had to deal with two cases in which the trouble arose from the proximity of a high wall a few feet from the side light. In the worst one the wall was higher than the studio, and about nine feet away. It was of dark brick, and how the previous occupant of the studio, for whom it was built, managed I cannot imagine. His work was certainly unorthodox, and he abandoned photography for the stage. Then during an interval it was occupied as a workshop, until its excellent business position attracted another photographer who decided to take the chance. The first thing to be done was to visit the owner of the wall and to ask his permission to have it painted white; this he gave readily enough, and the next to stipple the side light halfway up with very thin zinc white paint. The necessary dark and white blinds were fitted, and even in this dull weather the results obtained are excellent, although, of course, the exposures are not quite as rapid as they would be in a more open position.

Another studio was even in a worse situation, being located at the bottom of a deep well-hole surrounded by lofty houses. Before it was built I went on to the leads on which it was to stand, and certainly felt some misgivings; still it was there or nowhere, and as the prospective user was a wealthy man we decided to take the risk. There was toplight, and not too much of that, but, with the help of outside silvered reflectors, the lighting was quite passable, and many excellent portraits were taken in it. All cases are not so bad as this, but there are often obstructions which seriously reduce the value of a studio. Once I built a studio in a garden in the winter, and

it was very satisfactory, but what a difference when the leaves came on the trees again! Fortunately, most were on my own ground, and were drastically lopped, and my next-door neighbour helped, by cutting in one or two which still troubled me. It is wonderful what you can get done if you talk nicely to people. Here, again, I found that stippling the side light was an improvement, as light which would be nearly vertical is intercepted and dispersed in all directions. If rolled plate be used in such circumstances, there is a great gain in light if the ribs be placed horizontally in the side light; every rib becomes a little cylindrical lens, and throws light into the studio.

In the case of an immovable obstruction which is very near the proposed studio, it is advisable if possible to raise the building, so that it will overlook the obstacle. A friend who found himself in this difficulty said afterwards that it proved a blessing in disguise, for he had to provide himself with an excellent workroom upon which the glasshouse was built, and he found this much more comfortable than the cramped quarters he had proposed using, and the extra cost was not great considering the value of the accommodation provided.

When building or adapting a studio care should be taken to avoid minor obstructions caused by portions of the building itself; for example, I have seen a single slant studio in which the slant was obtained by throwing back the top behind the general line of the building, thus leaving a triangular piece of wall standing out at each end. This may not be serious in many cases, but if a front lighting is wanted it considerably curtails it, and this is more especially so when the studio is rather a short one, as the angle of light is then necessarily more acute.

Great caution must be exercised in erecting a studio near vacant land, as there is no guarantee that another building will not be erected that will shut the light completely out. In order to secure the right to do this, a landowner will often erect a screen on poles so as to block any window on neighbouring land in order to prevent any subsequent claim to "ancient lights."

It is easy to realise that different situations call for differently designed studios. In the commonest case of difficulty, where there is top light only, it is desirable to have as long a range of glass in the roof as possible, as we can then draw the blinds well over the sitter's head, turn him slightly away from the light, and get the effect of a high side light; such a studio should be built as wide as possible for this reason.

Studios of moderate height with side light only do not, perhaps, come within our scope, but as they, in common with those with top light only, are capable of being improved by the addition of a supplementary artificial light, we mention them. A top light may easily be produced under an opaque ceiling by using either the half-watt or an enclosed arc lamp in a metal reflector, which gives a strong though soft reflected light from the ceiling, while similar lamps may be used either to illuminate a white side wall or to give a direct side light through a diffuser. The mixture of lights is not at all objectionable, and, in fact, will hardly be noticed by many sitters.

Difficulties in lighting will be minimised if the studio be wide enough to allow of considerable latitude in the placing of the sitter; it should be possible to work diagonally or even quite across the studio, and it should always be arranged, if possible, that either end of the studio can be used.

When inspecting an empty studio or the site for building one, a very simple way of judging of its possibilities is to seat oneself in the position likely to be occupied by the sitter, and from there to note how much clear sky is visible, and the nature of any obstructions. This gives a good starting-point, and is better than attempting to judge the lighting, at all events, in the open air.

CHEMICAL FOG.

(A Paper from the "American Annual of Photography, 1919.")

If the sensitive emulsion with which a photographic plate is coated is examined under a high-power microscope, it is seen to consist of fine crystals of silver halide (chloride, bromide, iodide, etc., or complexes of these) embedded in gelatine. When light is allowed to fall upon these crystals they are affected in such a way that they are capable of being converted into metallic silver by certain chemical solutions known as developers, while the crystals not exposed to light remain unaffected. The process of converting the silver halide to metallic silver is called in chemical terms reduction, and the developer is called the reducing agent.

All reducing agents, however, are not developers. An alkaline solution of stannous chloride will reduce unexposed silver bromide, while a reducing agent like sulphurous acid does not affect it at all. Developers therefore lie between these two extremes, an ideal developer being one which completely develops all the exposed but does not begin to develop the unexposed crystals in the emulsion.

Most developers fall short of this ideal condition and develop a small proportion of the unexposed emulsion, producing a uniform veil or layer of silver over the entire plate which has the effect of obliterating fine shadow detail and diminishing the contrast. This fog produced by undesirable chemical action is known as "chemical fog," and it may be measured in terms of "density" in the same way as the silver image.

The amount of chemical fog produced in any particular instance depends on the following factors:—

I.—The Nature of the Emulsion.

A. The Type of Emulsion.—Photographic emulsions may be divided broadly into the following classes:

High and low speed negative emulsions.

High and low speed positive emulsions (lantern slides)

High and low speed paper emulsions (bromide and gas-light)

Chemical fog occurs most frequently during the development of high-speed negative emulsions, because in view of their highly sensitive nature and the infinitesimal amount of light—action required to render the silver halide developable, if the developer is too energetic or not compounded correctly it will develop the unexposed crystals also.

Low speed emulsions usually give images free from chemical fog providing a suitably restrained developer is employed, though it is somewhat of an anomaly that some developers will give clean images on high speed emulsions but will fog a slow emulsion like that on a lantern slide or positive motion picture film. It is therefore desirable in all cases to adopt the developer to the emulsion.

B. The Age of the Emulsion.—On keeping, all sensitive photographic emulsions become more or less fogged, the rate of formation of the fog being hastened by heat and the presence of moisture. Precisely what change takes place when the silver halide crystals are changed from the non-developable to the developable condition is not known. A large number of theories have been propounded, though these cannot be confirmed without further experimental investigation.

C. The Previous History of the Emulsion.—A new emulsion will give fog immediately if it is exposed to certain chemical agents, such as coal gas, sulphuretted hydrogen, or the vapours from benzol, turpentine, etc. The amount of fog produced depends on the concentration of the various chemical agents, the temperature, and the time of action. It is important therefore to store all photographic plates and paper in a cool, dry, well-ventilated place.

II.—The Nature of the Developer.

Fog caused by the developer is known as "developer fog." A developer usually contains four ingredients as follows:—

- (a) The developing agent (pyro, etc.);
- (b) The accelerator (sodium carbonate, etc.);
- (c) The preservative (sodium sulphite, etc.);
- (d) The restrainer (potassium bromide, etc.).

The amount of chemical fog (ignoring the presence of impurities) produced by a developer on any given emulsion depends on the proportion of each ingredient present, that is, on the particular developing formula employed. Considering each ingredient individually:

(A) The common developing agents, elon, hydroquinone, pyro and paraaminophenol (Kodolon) in actual practice appear to differ in their fogging power, elon and hydroquinone having a greater propensity for fog than the other two, though so far as our present knowledge goes there is little difference in the fogging power of the pure developers. The apparent differences are due either to impurities or to oxidation products of the developer formed either before or during development.

The oxidation products of paraaminophenol (Kodolon) produce very little fogging action even at high temperatures, and advantage may be taken of the fact when developing under tropical conditions. (See "British Journal," 1917, p. 555.)

The limiting proportion of the developing agent to be used in any formula can only be found by trial, though this does not usually exceed 10 grams per litre for economical reasons. Increase in the proportion of elon beyond this usually gives fog, though in the case of hydroquinone an increase in the proportion may prevent fog. The following formula will give extreme contrast on a positive emulsion without fog when used for reel development, whereas a reduction of the proportion of hydroquinone to, say, 5 grams would give fog before any great contrast was obtained:

Hydroquinone	25 g.
Sodium sulphite (desiccated)	33 g.
Sodium bisulphite	3.3 g.
Sodium carbonate (desiccated)	66 g.
Potassium bromide	1.5 g.
Water to	1000 cc.

(B) The accelerator, in the form of carbonates or hydroxides of lithium, sodium, potassium, or ammonium, is added to accelerate the developing action of the developing agent. If too much is added, the developer passes from a true developer to a fogging agent, that is, its reducing power is so great that the unexposed portions of the emulsion are reduced to metallic silver also. The correct proportion of accelerator to be added in any case can only be found by trial. Amidol does not require the addition of an alkali, while in the case of hydroquinone, if sufficient sulphite is present, the proportion of sodium carbonate in many cases may be increased from 25 to 100 grams per litre, without increasing the amount of fog produced.

(C) Sulphite, in the form of sodium sulphite, bisulphite, or potassium metabisulphite, is added to prevent oxidation of the developer by the oxygen present in the air, which would otherwise cause oxidation fog. The proportion necessary to prevent undue oxidation is usually equivalent to 50 grams of sodium sulphite per litre, though if sulphite is added in considerable excess of this sulphite fog is produced.

The nature of sulphite fog has been carefully investigated by Mees and Piper ("Phot. Journal," 1911, p. 226, 1912, p. 221), who found that silver bromide is appreciably soluble in

sodium sulphite, so that sulphite fog is caused by the reduction to metallic silver of the silver salt dissolved away from the emulsion by the sulphite in the developer.

The proportion of sulphite used determines the keeping qualities of the developer, but if an excess is employed more or less bromide must be added to compensate for the sulphite fog otherwise produced.

D. The restrainer in the form of sodium or potassium bromide or iodide is added to the developer when mixed in order to prevent chemical fog. In cases of known over-exposure bromide is of course added, though when mixing the developer only sufficient bromide should be added to compensate for any impurities or slight fogging tendency of the developer used.

III.—Impurities in the Developer.

Impurities in the developer are the chief cause of development fog and they may be divided roughly into two classes as follows.—

A. Oxidation Products Formed During Development.—During development several oxidation processes are going on. (1) the developing agent is being oxidised by the air, and (2) the developing agent is being used up by virtue of its reducing action in changing the exposed silver salt to metallic silver. In so doing it is oxidised itself, the product formed being usually identical with that produced by aerial oxidation. The oxidation products formed in this way usually exert a powerful fogging action, especially in the case of metol and hydroquinone. The oxidation product of pyro, which is present when the pyro developer turns brown, exerts little or no fogging action except when present in strong solution.

A third oxidation process taking place is "sulphite oxidation" or the formation of sodium sulphate together with hydroquinone mono and disulphonates. (*Zeit. Wiss. Phot.*, 1913, p. 289). Sodium sulphate is not a fogging agent, while hydroquinone disulphonate exerts a protective action on the oxidation of hydroquinone (*loc. cit.*), so that the sulphite (if not present in excess) affects the fog produced only indirectly according to its protective action on the developing agents.

The reason why sulphite protects a developing agent from aerial oxidation is not known, it being generally supposed that the affinity between oxygen and sulphite is greater than that between oxygen and the developing agent. The life of a developer before it gives excessive fog depends on so many factors, such as the catalytic and anticatalytic action of the oxidation products of the developing agent and sulphite, that it is difficult to differentiate between the various effects.

It has been observed, however, that the rate of formation of fog varies in proportion with the rate of oxidation of the sulphite. Thus a small trace of copper will accelerate the rate of oxidation of a sulphite solution and produce fog in a developer, while the rate of oxidation of a pure sulphite solution decreases as the concentration increases. Taking advantage of this fact a developer formula suitable for developing motion picture positive film by the reel method (which gives fog with the common developers except glycin) was worked out by the author of this paper as follows:

The method of procedure was to fasten the film on the periphery of a small metal reel and to rotate this while dipping into a tray of the developer maintained at a constant temperature.

The following formula was taken as a working basis, and the proportion of the constituents A and B varied as follows:—

Elon5	gram
Hydroquinone	10	"
Potassium bromide	3.5	"
Sodium sulphite (desiccated)	A	"
Sodium carbonate (desiccated)	B	"
Water to	1000	ccs.

Effect of Varying the Sulphite Content.—While B was maintained constant and equal to 100 grams, A was varied as follows:—

Time for Fog on Cine Positive at 80° F.	
A 25 grams	3 mins.
50 "	3½ "
75 "	5 "
100 "	6 "
125 "	7 "
150 "	6 "

Any increase in the sulphite content beyond 100 grams considerably retarded the rate of development, and as a minimum of fog was produced at this point, 100 grams was considered to be the most suitable proportion.

Effect of Varying the Carbonate Content.—A was maintained constant, equal to 100 grams, and B varied as follows:—

Time for Fog on Cine Positive at 80° F.	
B 25 grams	3 mins.
50 "	3½ "
75 "	4½ "
100 "	5 "
125 "	5 "
150 "	4½ "

The least fog is therefore produced when the content of both carbonate and sulphite is equal to 100 grams.

The most suitable formula is therefore:—

Elon	0.5	gram
Hydroquinone	10	"
Potassium bromide	3.5	"
Sodium sulphite (desiccated)	100	"
Sodium carbonate (desiccated)	100	"
Water to	1000	ccs.

The effect of dilution of this formula was to increase fog as follows:—To 100 volumes of the developer C volumes of water were added.

Time for Fog on Cine Positive at 80° F.	
C 0 vols.	5 mins.
50 "	3 "
100 "	2 "
150 "	2½ "
200 "	3 "

In practice on the large scale, the above developer was found to give positives remarkably free from fog even after continual use with the temperature of the developer and surrounding atmosphere at 80° F.

It was found that if the developer was splashed on the floor during working, this crystallised out and caused trouble due to particles of sulphite and carbonate dust settled on the film. This was overcome by replacing the sodium carbonate by an equal weight of desiccated potassium carbonate, since owing to the deliquescent nature of the latter, any liquid splashed around did not dry up but remained moist. The developer containing potassium carbonate was also somewhat more energetic than the one containing sodium carbonate.

The increase of the fogging action on dilution is probably due both to the increased rate of oxidation of the sulphite on dilution, and to the increased rate of penetration of the developer, since on dilution the velocity of development increased also.

The above developer is more economical than the developer according to the formula first given in this article, which contains more hydroquinone but less sulphite. The non-fogging properties of this developer are probably due to the anticatalytic action of the products of oxidation of the hydroquinone on the rate of oxidation of the sulphite and the hydroquinone.

A possible explanation of the cause of excessive fog during reel development is the heat produced by the oxidation of the sulphite, the finely divided silver image possibly acting in the same way as finely divided platinum which accelerates the rate of oxidation of coal gas in the case of the familiar gas lighter.

B. Oxidation Products formed while Mixing the Developer.

—Although a developer formula usually contains enough sulphite to prevent excessive aerial oxidation during development, oxidation products may be formed during mixing if the developer is not mixed correctly. It is important to observe the following rules.

- (1) Dissolve the preservative before adding the developing agent.
- (2) Thoroughly dissolve the developing agent before adding the carbonate.
- (3) Mix the developer as cold as possible.

If the developing agent is dissolved first before adding the sulphite, the small amount of dissolved air in the water is sufficient to form enough oxidation product to cause fog.

In the case of elon, add only a small portion of sulphite first, then dissolve the elon and add the remainder of the sulphite. This procedure is necessary because elon forms a difficulty soluble compound with sulphite and will therefore not dissolve readily in a cold strong solution.

If the carbonate is added to the solution before the developing agent is dissolved, each crystal becomes oxidised at the surface, thus causing fog.

A third cause of fog is mixing the developer too hot. Heat accelerates the rate of oxidation of the developing agent, especially after the carbonate is added, and if the concentration of carbonate is high, even if the developer is mixed in the right order, it will give fog if mixed warm. In the case of developers containing no bromide used for testing the quality of plates and for developing under-exposed negatives it is absolutely necessary to mix the developer with cold water if a minimum of fog is desired.

Oxidation products are usually formed in the developer on keeping, though most developers will keep for a long time if kept thoroughly stoppered in a full bottle free from air.

A developer should at all times be as colourless as possible. In the case of an elon-hydroquinone developer, the fog produced usually varies in proportion to the colour.

C. Impurities in the Chemicals Used.—Fogging agents may be present as impurities in the chemicals used as follows:

(1) *Oxidised Products of the Developer Formed During Manufacture.*—If the elon, hydroquinone, or pyro used is strongly coloured the presence of fogging agents may be suspected, though some coloured samples do not give any more fog than colourless ones. The way to test a developer for fogging tendency is to mix two developers according to the same formula, one with the sample, the other with a pure sample, and to develop unexposed strips of motion picture positive film, noticing the time required for fog to just appear at 70° F. The fogging power of the developers is then in the inverse ratio of the times required to produce fog.

(2) *Impurities in the Developer.*—Many metallic compounds, such as salts of copper and tin, metallic sulphides, etc., exert a powerful fogging action even when present in very minute quantities. Less than .01 per cent. of copper sulphate when added to an elon hydroquinone developer will cause fog on most positive emulsions. The precise action of such a minute trace of copper is not thoroughly understood, presumably it acts as a catalytic agent in accelerating the rate of oxidation.

Red rubber tubing when used for conveying developing solutions is a common cause of fog owing to the solvent action of the carbonate in the developer on the antimony sulphide present as a filler in the rubber.

Stale sulphite which contains sodium sulphate will cause fog indirectly since the deficiency of sulphite will allow oxidation to proceed more easily.

Dissolved salts present in the water used for mixing the developer, unless of the above nature, seldom produce fog.

IV.—Effect of Exposure and Time and Temperature of Development.

(a) When silver bromide is developed to metallic silver with a hydroquinone carbonate developer, sodium bromide is formed in proportion to the amount of silver developed according to the following equation:—

In cases of full exposure therefore an appreciable amount of bromide accumulates in the developer, and this restrains the formation of chemical fog. This can be shown experimentally by developing an unexposed and a fully exposed plate side by side in separate trays for, say, 10 minutes, when the unexposed plate will be seen to be fogged more than the unexposed portions of the negative. The extent of the restraining action of the bromide thus formed depends on the volume of the developer used, so that in order to reduce its effect to a minimum a generous supply of developer should always be used, and the developer well agitated.

(b) Fog appears after a certain definite time interval after development commences depending on the nature of the developer, the emulsion and the temperature, and then continues to increase proportionally with the time of development. If the volume of the developer is small the bromide formed as a product of development will, of course, retard the production of fog as explained above.

As a general rule the temperature of the developer should not exceed 70° F. nor should development be unnecessarily forced in case of under-exposure, because after the maximum contrast has been secured, that is when the latent image is fully developed, fog still continues to form. An ideal developer is therefore one which gives the maximum contrast before the emulsion begins to fog, and such a developer can only be found by trial with the particular emulsion used. As mentioned above, paraminophenol (Kodolon) most nearly approaches this ideal condition with negative emulsions, even at temperatures above 70° F.

Methods of Compensating for Chemical Fog.—(a) The amount of fog produced by a developer may be reduced by adding a soluble bromide or iodide to the developer before use. The precise action of a salt like potassium bromide is not thoroughly understood though it may be explained from physico-chemical considerations, the added bromide diminishing the solubility product of the silver bromide which is about to be developed. Potassium iodide probably converts a portion of the silver bromide grains to silver iodide, which develops with difficulty.

(b) If the emulsion tends to give fog this may be compensated for by adding bromide or iodide to the developer as above, though in the case of photographic paper the colour of the developed image is affected.

It is also possible to treat gaslight paper in a bath consisting of a mixture of potassium bichromate and sodium chloride, afterwards washing and drying, thereby converting any fogged silver grains to the unfogged condition, though the process diminishes the general light sensitiveness of the emulsion.

Dichroic Fog.—This is a particular kind of fog which occurs only on negative plates, films, and lantern slides as a more or less uniform veil over the gelatine coating. When examined by reflected light the deposit appears yellowish green, while by transmitted light it appears reddish pink, hence the name "dichroic fog," which means "two-coloured fog."

When examined under the ultra microscope the fog is seen to consist of ultra microscopic particles, which by chemical analysis have been shown to consist of metallic silver. The size of the particles determines their colour by transmitted

light, a fog which is red in colour consisting of very small particles.

Dichroic fog may be formed either in the developer or in the fixing-bath. In order that the deposition of the fog may take place in the developer some solvent of silver bromide, such as hypo, ammonia, or an excess of sulphite or carbonate must be present, when under certain conditions the dissolved silver is reduced to metallic silver in a very fine state of division, particularly in the shadow portions of the negative, where no bromide is liberated during development.

Fine grained emulsions in which the grains of silver halide are very small and therefore more readily soluble are most susceptible to this form of fog, especially if the development is forced, but the fog may be prevented by the addition of a little potassium iodide to the developer.

The difference between the cause of sulphite fog and dichroic fog appears to be merely a question of the time interval between solution and reduction of the silver.

The formation of the fog most generally occurs during fixing, especially if the fixing-bath does not contain acid or if it is old and exhausted, when it contains an excess of dissolved silver and spent developer. It is possible to obtain dichroic fog with a fresh solution of plain hypo, in which case the silver salt dissolved by the hypo is reduced to metallic silver by the developer carried over by the plate to the fixing-bath. This is especially true if the gelatine coating of the plate is abnormally thick and if the developing and fixing solutions are warm. In such a case the developer does not have time to diffuse out of the gelatine film before the hypo begins to dissolve away the silver bromide. A fixing-bath containing ammonium chloride (which is added to accelerate the rate of fixing) will give dichroic fog unless the bath is kept acid, in view of the ammonia liberated by the action of the alkali in the developer carried over by the plate.

Dichroic fog never occurs in the fixing-bath if a fresh acid bath is used and if the plate is rinsed before fixing. If dichroic fog still persists when using an acid fixing-bath at a temperature not above 70° F. the trouble lies in the developer.

J. I. CRABTREE.

THE VALUE OF EXPRESSION IN PORTRAITURE.

A MATTER to which many portrait photographers do not give the consideration that it merits, is the expression of the sitter's countenance at the moment of the exposure. In my experience and observation the one thing more, perhaps, than any other single quality, which secures approval or disapproval of a portrait, is the sitter's expression. I was speaking in this sense recently to an old photographer, now a director of a firm having several studios of good class, and he replied that he would undertake to build up a business by attention to the matter of the sitter's expression, when on technique he could not do so. It is not to be supposed that the speaker thinks slightly of the importance of good sound photography. He recognises, as I do, that that should be the foundation on which our work should be based, but that for securing the satisfaction of our patrons he considered the presentation of a pleasing expression to be the most important factor.

To some extent the desirability of securing an agreeable expression in a portrait has been recognised from the early days of professional photography. A stook wheeze of the "comic" papers has been to represent the photographer as telling the sitter to "look pleasant." There may be photographers who use this formula; I don't remember that I ever did so. A sitter, unless in the case of a skilful actor, does not look pleasant to order. I have often known a fond mother say to her baby or young child when ready for the sitting, or even before that, "Now laugh, laugh." I have never known this to succeed. The child is too young either to understand the injunction, or to be able to take the part of an actor and assume an expression not actually in accordance with its feelings. Some playful antic on the part of the photographer is much more likely to produce the desired effect. I have often found a little game of Peep-bo to succeed in attract-

ing baby's attention and in securing an interested expression. With sitters other than infants, conversation will naturally be the means employed. With boys a little discussion as to the relative appreciation of trigonometry and football or cricket will often induce an amused expression, but here some tact is desirable. An opening sentence or two will generally show the direction into which to guide the conversation. The leading principle is not to tell the sitter to assume any particular expression, but to say or do something likely to evoke it.

With adult sitters, tact and the avoidance of anything like taking a liberty are of the highest importance. I have known a photographer, thinking to chase away a mournful expression, tell a lady not to look as if she were in a consumption, only to be crushed by the reply, "Perhaps I am."

A photographer ready to turn to advantage any little incident that may occur may often succeed in obtaining a happy expression that will secure a good order from the negative. One such case that occurs to me is that of a young lady of German parentage, born or long domiciled here (this occurred long before the war). The young lady had good features, but when posed for the photograph assumed a stern, almost forbidding, expression which ordinary conversation failed to remove. Presently, however, her mother said something to her in German, on which I joined in with "Ach! Wenn ich nur Deutsch verstehen könnte!" (Oh! if only I could understand German!), which, being spoken in the language of which ignorance was assumed, so tickled the lady that she burst out laughing. When the ripples of laughter had subsided but an amused expression still hung about the features, a very successful portrait was secured. With French sitters, of whom there have been a good many this year, I have found that a little conversation in their own language generally induces an interested expression even if they speak English well, and particularly if they do not do so.

Since commencing to write this article I happened to be in the studio of a photographer who does a high-class business at good prices—he refuses altogether to take negatives for postcards—when a lady came in bringing with her a friend for a sitting. The lady complimented the photographer on her own portrait, which she said was the only one that she had with a satisfactory expression, and that she was really rather ashamed of having given away such a large number of her own portraits. Depend upon it, there is more in the value of the expression in portraiture than most photographers realise.

W. E. DEBENHAM.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

REPORT OF THE COUNCIL FOR 1918.

DURING the year 151 new members have joined the Association. As it is in some cases impossible to determine whether a member who has joined up is to be considered as continuing to be a member, it is not possible to give the precise membership of the Association, but the fact that there are 915 subscriptions which have been paid during the current year shows that the progress of the Association may be considered satisfactory.

The following table shows the subscriptions collected for the past five years.

1914	...	772	Congress.
1915	...	812	"
1916	...	729	No Congress.
1917	...	888	"
1918	...	915	"

At the last annual general meeting a resolution was passed "That the Council be requested to consider the practicability of training and employing disabled soldiers and sailors as photographic workers, and make a report." The Council had considerable difficulty in determining how to deal with the matter, from the fact that the precise matter the Council was requested to consider could not possibly be that implied by the literal reading of the resolution, it being obvious that many forms of disablement would not materially affect those who suffer from them so as to prevent their being trained and employed as photographers, and upon the question whether it would be wise to encourage the idea that after a short training in photography anyone of ordinary capacity would be able to acquire sufficient knowledge and skill to earn a livelihood, which appeared to be the true object of the reference, the answer was so dependent

upon the situation after war, the end of which was not then in sight, that the Council could not express an opinion. The report issued stated at length the considerations involved and the reason the Council could not offer a definite opinion.

The Council have to thank Messrs. Kodak, Limited, and the Editor of the "Professional Photographer" for their kindness and courtesy in printing our President's appeal to photographers to join the Association, and also inserting an application form, the result being the accession of about ninety new members. Thanks are also due to the Editor of the BRITISH JOURNAL OF PHOTOGRAPHY for inserting reports, information, and helpful references to the Association's work.

Negotiations between the Royal Air Force, urgently in need of photographers, and the Association, anxious to assist the R.A.F. in their need by finding qualified men, resulted in our efforts being rendered unavailing owing to the extraordinary attitude of the R.A.F. officials. A full account of what happened has been published in the "P.P.A. Circular."

Owing to the difficulties of resettlement after the disorganisation caused by over four years of warfare, the Council have not been able to arrange for a Congress in 1919, but arrangements are already being made to hold one in 1920, which, it is hoped, will be as beneficial to members as the five previously held.

On the institution of the Society of Master Photographers (Lancashire and District) application was made to the Council for affiliation to the Association; as the activities of the new Society covered a wide-spread district, in that way differing from a local branch, the Council acceded to the application.

Before the end of the war was in sight the Council were preparing to take the necessary steps to secure early discharge for such of the members who were serving in the forces and anxious to return to their businesses, and the necessary steps were taken, as far as military conditions would allow, to act at the proper time. After the armistice, on the Government scheme of demobilization being published, it was found to be of such a nature that no application of the Association would be of further avail than his own or of that of his wife or other relations, and that any cases of undue detention would be due to faulty administration and not to defect in the method of the scheme.

In the last annual report it was mentioned that the Fine Art and General Insurance Company had given notice to terminate their arrangement with the Association. The Council have entered into a new arrangement with the Eagle, Star, and British Dominions Insurance Company under which members can have their insurances effected on the same terms as before. The new arrangement has been in force since May last.

Meetings of the Council have been held monthly throughout the year. The attendance of an average of sixteen members of a total of twenty-seven, thirteen being country members, is evidence of the continued interest in the Association of those who are responsible for its management.

The "P.P.A. Circular" has been published with regularity during the year, and judging from the appreciative references, has assisted the Association work and brought its members into closer touch with each other.

Parliament, having agreed upon the principle of a tax upon luxuries, appointed a Select Committee to consider and report what articles ought to be classed as luxuries subject to the tax, and the representative organisations of various trades and others interested were invited to appear before the Committee and state their views as to the adjustment of the duty to the articles in which they were interested. As the interests of photographers as a profession are identical with those of the photographic manufacturers and dealers, an arrangement was made with Mr. Edgar Houghton, President of the former and a member of the Council of the latter Association, who was to appear before the Committee on behalf of those Associations, to represent our interests also. It had been intimated that the schedule of the French Luxury Tax would be taken as a basis for the British schedule, the articles affecting photographers in the latter being—

Photographs, portraits, exceeding in price, per dozen, 40 francs.

Photographs, enlargements, exceeding in price, each, 30 francs.

On our behalf it was submitted that the limit of price for our own Act should be—Photographs, portraits, exceeding per dozen 42s., and enlargements 30s. each.

On the report of the Select Committee being published it was found that the limit of price we suggested had been adopted, but by the omission of the word portraits, the tax was made to apply to photographs of any kind. As, clearly, many descriptions of photographs, such as those taken for commercial, technical, and scientific purposes, cannot justly be regarded as luxuries, on the introduction of Mr. Lang Sims a deputation of the Council had an interview with Mr. Davison Dalziel, a member of the Select Committee, to represent our views. On stating our case, Mr. Dalziel expressed his appreciation of the position and his concurrence with our views, and promised to represent this aspect of our case to the Chancellor of the Exchequer.

Should taxation on the same lines form part of the next Budget, the Council are preparing to watch proceedings in the interests of our members.

THE BRITISH INDUSTRIES FAIR

THE fifth of the "Fairs" organised by the Department of Overseas Trade is this year again held in the Pennington Street premises of the London Docks, a horribly inaccessible position, but one which certainly provides abundant space for the large number of stalls. The Fair is limited to British manufacturing firms engaged in the trades concerned with porcelain, china and glass, fancy goods, stationery and printing, paper, toys, and games. The firms whose manufactures possess a photographic interest are chiefly to be found in the K Section devoted to stationery and paper, but some others are located in other sections.

Frames and mouldings form a large exhibit of Messrs. Bennett and Jenkinson, Limited, Wellington Works, Grimsby, whose manufactures in the way of wood mouldings and frames of all descriptions are well known in the photographic trade. Their distinctive goods, consisting not only of ornamental wooden frames, but of those in metal, are shown by Messrs. Marion and Foulger, Limited, 3, Soho Square, London, W.1.

In mounts the most attractive display is that of Messrs. Bartons, Conway Works, Finch Road, Handsworth, Birmingham, who give great prominence, but no more than the artistic quality of the articles merit, to their "Quadro" metal passe-partout framing, the effectiveness of which for both large and small work is very convincingly shown. Albums of many types are shown by the old-established firm of William Johnson and Sons, 8, Union Street, Southwark, London, S.E.1; whilst some distinctive styles in mounts, designed for use in connection with memorial photographs, are exhibited by Argent Archer, 140, Kensington High Street, W.8.

From mounts to mountants is a natural step, and we were interested in seeing at the stall of the Leadenhall Press, 29 47, Garden Row, Southwark, London, S.E.1, exhibits of adhesive pastes for photographs, which are issued not only in the glass pots for amateur use, but are sold in bulk to professionals. The firm has also a cheap but highly adhesive paste, marketed as "Fixol," which, though it is not issued as a preparation of the highest degree of purity demanded in a photographic mountant, is nevertheless one which in these days of development prints could be used for mounting purposes. It is certainly a preparation which is applied in the smoothest manner, but possesses extraordinary adhesiveness. A gum preparation for the mounting of photographs and albumen colours for the tinting of photographic prints, lantern slides, etc., are among the exhibits of the British Drawing Ink and Adhesives Manufacturing Company, 31, Great Ormond Street, London, W.C.1.

The rotary printing of postcards and other descriptions of photograph, such as those for box covers, calendars, cigarette stiffeners, and other commercial purposes, is represented by a number of firms. The Rotary Photographic Company (1917), Limited, West Drayton, Middlesex, now a British concern, shows a wide range of its productions, including a large proportion of coloured postcards. Messrs. Philip G. Hunt, 332, Balham High Road, London, S.W.17, give prominent display to their old established connection with this business, and particularly to their facilities for supplying series of view postcards from their own stocks of negatives. Messrs. Lilywhite, Limited, Dunkirk Mills, West End, Halifax, Yorks, show examples of their specialties in the same industry, among which are humorous cards in three colour, postcards for seaside sale, and photo-cut outs and paste-ons for the jewellery, framing, and other trades. Messrs.

F. T. W. Dennis and Sons, Ltd., Printing House Square, Scarborough, also show their productions in this line.

The exhibits of the pencil makers, an industry which, it may be hoped, now supplants the Austrian output, are of interest mainly from the fact that retouching leads for use in the customary metal holder are among the specialties of both Messrs. Arthur Johnson, Limited, Britannia Pencil Works, Neasden, N.W.10, and Messrs. F. Wolff and Son, Limited, 82, St. Thomas Street, London, S.E.1.

Among other miscellaneous exhibits must be mentioned the fine reproduction work of the Rembrandt Intaglio Company, Queen's Mill, Lancaster, and the Sun Engraving Company, Limited (formerly André Sleigh and Anglo, Limited), Milford House, Milford Lane, E.C.2. Messrs. Wiggins, Teape and Company, Limited, 10-11, Aldgate, London, E.1, although having large interests in the manufacture of ledger, cartridge, blotting, and writing papers, devote their exhibit almost exclusively to photographs illustrating the raw paper base which during the war they have manufactured in increasingly large quantity, and for which they are laying down a special mill. H.M. Queen Mary, on her visit to the exhibition on Monday last, expressed herself interested that the British paper-makers were rendering the manufacturers of photographic materials independent of enemy products. The Aerograph Company, Limited, 43, Holborn Viaduct, London, E.C.1, show examples of their goods not only in the colouring and working-up of photographs, but of the many industrial applications of their air-brushes. The Tella Camera Company, 1, Southampton Row, London, W.C.1, exhibits its work in commercial and technical photography and illustrations. At the stand of Messrs. A. E. Gray and Co., Ltd., Glebe Works, Mayer St., Hanley, Staffs, we saw specimens of grooved tanks in semi-porcelain, as used for development and fixing. Mr. Thomas Bethell, Boundary Place, Liverpool, shows in the toy section the cardboard cameras and dark-slides by which, for many years past, children have been able to make a first acquaintance with photography at the cost of a few shillings.

It should be said that the Department of Commercial Intelligence, in organising the Fair, undertakes no small amount of investigation into the *bona fides* of the exhibitors, in respect to their being actual manufacturers and of British constitution. Admission to the Fair is understood to be by invitation of the Department, but we imagine that any *bona fide* buyer who wishes to visit the Fair will receive consideration on application to the Department at 10, Basinghall Street, London, E.C.2.

Assistants' Notes.

Celluloid Facing.

PHOTOGRAPHIC miniatures, which are so popular with the working-classes, are easily made; the important factor is the time taken up. By means of the card repeating back four-pictures are made on a quarter-plate. Sometimes the original requires the background painted out with Chinese white, or a few touches put in with lamp-black water-colour to make a bold effect. Of course, these touches are sponged off after making the negative, which should be on the contrasty side. Four pictures are made on one piece of glossy paper to give sharp detail, and then coloured by dyes. Celluloid facing gives an enamelled appearance, and by its attractiveness helps the sale. For cementing without hot rollers use 4 parts methylated spirit, 1 part amyl acetate. Do not increase the amyl acetate unless the celluloid is thick. This is best for gelatine papers, such as glossy P.O.P. and bromide. Do not use this with collodion papers, as it dissolves the image. Cut a piece of celluloid a little larger than the print, put a few drops of above in the middle of same, then press from the centre all round outwards, in contact with blotting-paper. By making the facing little larger than the print the excise cement reaches the blotting-paper and does not get on the face of picture spoiling the high gloss. With a little practice the right number of drops will be found, and no air bells formed. Major's cement, which is gelatine dissolved in glacial acetic acid, is more suitable for collodion papers, is slow in working, and if you use this cement for glossy P.O.P. and the picture should slip in the pressing down, you will find the acid has softened the image and the movement blurred the picture. Collodion papers are not suitable for dye work.—BURLINGTON.

Photography with the Royal Engineers.

ACCOUNTS of the part that photography has played in the war have so far been written principally in terms of aircraft observation. While no doubt this branch has employed more men and material than any other, and has been both organised and advertised in the energetic and efficient way characteristic of the Air Force, there has been a vast deal of photography done in connection with other departments that should not be lost sight of in considering photographic war-history. The work of official photographers of a kind that used to be done by war correspondents is, of course, also well known, as is the development in radiography; but the photography carried out by men of the Royal Engineers has been not only extensive and varied in character, but it has not met with the recognition that its importance and quality deserves.

Of work that takes the operator well up into the danger zone is the making of panoramic views of enemy trenches and territory. Then there is "sound-ranging." This is a marvellously ingenious and scientific method of locating enemy guns very exactly. The apparatus was invented by a Frenchman and improved by us, and as the Germans have never succeeded in capturing an instrument nor in remotely approaching the idea in efficiency, this has been a great factor in our success. The part of the photographer in this branch calls for decreasing knowledge and skill as the instrument is improved, but it calls for mention in a record. This is only one of the many rapidly growing activities of a Field Survey Battalion. These units are more generally known in the Army under the concise and expressive name of "Maps."

Enormous quantities of maps are plotted, drawn, and printed "in the field," and the photographer has his share in reproducing them to various scales, both on wet and dry plates, including, of course, panchromatics. Many of the workers are old "Ordnance Survey" men, but they are not now by any means in the majority. Besides the operators there are men who print the line negatives on to zinc plates for the lithographic printers, and those who print in special variable details by true-to-scale processes. Then there are the highly skilled "glass engravers," as they style themselves, or "negative-scratchers," as would-be humourists call them. Their work, delicate and tedious, done principally with a finely sharpened needle and a magnifying glass, is at its best compared with ordinary commercial retouching as the latter is to scene-painting.

In a published account of the success of the Intelligence Corps were mentioned, in passing, the expert photographers as assisting in its work. These also are men of the Royal Engineers. The field of photography even here is varied enough to try the skill of the best. Copying and printing in large numbers portraits of suspected persons is only one small item. These often have the unmistakable appearance of being already copies of the third or fourth generation—if I may use that expression—and badly done at that; so that to make good printing negatives to give useful results is not always easy. Copying documents and posters to be used in convicting enemy officers of illegal executions is work that one could take pleasure in, notwithstanding the weird colours and crumpled conditions of some of them. Photographing parts of captured mechanism for various departments is frequently required, and even work of very technical and experimental character is successfully coped with, although it will be recognised that material, when it arrives at the place of use, often has already had a long history of careless handling and bad storage behind it, and, therefore, cannot always be considered as of A1 category.—D. CHARLES.

Ply Wood.

THREE-PLY wood is now available for photographic purposes, the various restrictions having been withdrawn, and is a useful material for either carbon transfer or for mounting enlargements. Card-board mounts require a further backing of wood when framed, whereas a picture mounted on ply wood would go straight into the frame, having a nice appearance at the back; so if we take this advantage into account the price will compare favourably with card-board. Ply wood is made in various woods, up to seven-ply for special use, but for mounting purposes three-ply birch, which can be had "free from knots one side," will answer studio requirements. The albumen in the wood, by steam treatment, is made somewhat insoluble; though some call it "waterproof three-ply," it certainly is less absorbent than the ordinary sort, and less liable

to wood-worm. It does not split like ordinary panels, is superior to canvas, as holes cannot be knocked through it, can be got any size and cut any size, stretchers are dispensed with, and is the material the old masters would have welcomed with open arms.—
BURLINGTON.

Patent News.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

PRINT WASHERS. No. 122,371 (January 18, 1918).—To receive the prints there is employed a preferably oval basin for water in which the prints may be immersed, the basin being formed with pockets communicating with the interior of the basin by way of perforations in the side, and being formed with a double bottom the inner member of which is perforated.

FIG. 1

Characteristic of the invention is the formation of the interior of the basin where the side wall joins the bottom as a concavely curved surface, above which are ribs presenting convex surfaces whereby prints or the like are kept from adhering to the side of the basin.

FIG. 2.

In the drawings the conduit pipes 13, 14, 15, and 16 deliver water to the basin, the pipes 13 and 15 being led to the pocket 24 outside the basin 5, and the pipes 14 and 16 being led to

the pocket 28. The basin 5 communicates with the pockets 24 and 28 by way of perforations in the side of the basin.

The basin is drained from the bottom by a waste pipe 31.

To prevent prints from getting into the pipe 31, the basin is formed with a double bottom of which the inner member 27 is perforated and formed with an undulating surface—with the object of assisting in separating and turning over prints that may tend to sink.

34 denotes internal ribs on the side of the basin preventing smooth convex surfaces.

At the junction of the vertical lateral wall of the basin with the inner member 27 of the bottom the inferior of the basin is concavely curved as shown at 35.—Peter Hugh Waddell, Troon, Ayrshire

PRINT-DRYING MACHINES.—No. 121,936 (Sept. 24, 1918).—The invention relates to machines for drying blue prints and other photographic copies of drawings and to that class of such machine wherein a heated cylinder has arranged in combination with it an endless band mounted upon rollers, so located that the band bears against a considerable portion of the surface of the cylinder and wherein the cylinder and band are caused to move at the same surface speed, so that sheets of paper inserted between them will, as the cylinder is rotated, be maintained in contact with it for a sufficient time to dry.

The drying cylinder is arranged in an open frame, and one end of the cylinder is provided with external teeth with which a pinion, on the shaft of one of the rollers around which the travelling apron runs, engages, so that when the said shaft is rotated the drum and apron will be simultaneously operated.

The frame of the machine is preferably constructed of corner

bars, a, a of angle metal united by longitudinal bars b, b and transverse bars c, c

The drying cylinder is provided with end discs e, e to which tubular hubs or bosses are fixed, these bosses being mounted in bearings y, y in the frame and having a gas-pipe h for the heating burner extending through them in the usual manner. The gas pipe, as shown, is carried in eye bolts i, i, and a space may be left between the pipe and the bosses for the admission of air to the drying cylinder. k indicates the travelling apron and l, m, n, o, the rollers upon which it is mounted

To one end of the cylinder is fixed a ring p having peripheral teeth, and on the shaft of the roller o is a pinion q engaging with the teeth, so that as the shaft is driven the cylinder also will be rotated and the apron k at the same time caused to travel. These teeth may be formed by securing a pitch or sprocket chain around the cylinder or a ring thereon, with which links the pinion will be adapted to engage.

The shaft of the roller o is driven by a worm r and worm wheel s , the shaft t on which the worm is mounted preferably receiving its motion from an electric motor through a band or belt running on a pulley u .

Holes v, v are formed in the ends of the drum, some of which may be provided with movable covers w, w for regulating the temperature of the drum by controlling the escape of the products of combustion and the admission of air.

To regulate the tension of the band or apron k the bearings of the roller m are suspended by links x from levers y, y , pivoted on the frame and provided with adjustable weights z, z .—Sydney Harold Morse, Finsbury Pavement House, London, E.C.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, MARCH 1.

Edinburgh Photographic Society. "Sir David Wilkie, R.A." R. T. Skinner.

MONDAY, MARCH 3.

Bradford Photographic Society. "An East Coast Ramble." W. H. Atkinson.
Dewsbury Photographic Society. "York City and its Minster." A. T. Dawson.
South London Photographic Society. "Sketch Portraiture." H. C. Inakeep.

TUESDAY, MARCH 4.

North Wilts Field and Camera Club. "Photographic Odds and Ends." C. L. Richards.
Hackney Photographic Society. Selection of Slides by A. J. Linford and W. Selle.
Chelsea Photographic Society. Dark Room.
Royal Photographic Society. "Hints and suggestions for use in the dark-room and work-room." V. Jobling.

WEDNESDAY, MARCH 5.

Croydon Camera Club. "More Curiosities seen under the Microscope." G. Ardaseer.
Dennistown Amateur Photographic Association. Annual General Meeting.
Tunbridge Wells Amateur Photographic Association. "The Swiss Alps." R. Gorbod.

THURSDAY, MARCH 6.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A meeting of the Council was held on Friday, February 14. Present: Messrs. A. Basil, Gordon Chase, A. Corbett, A. Ellis, S. H. Fry, W. E. Gray, R. Haines, G. Hana, A. Mackie, Lang Sims, R. N. Speaight, M. Adams (Reading) F. Brown (Leicester), W. B. Chaplin (Windsor), I. Chidley (Chester), and Montague Cooper (Taunton).

The Chairman said that the meetings were now extended to such length as to cause serious inconvenience to many members. Meeting at 6 it constantly occurred that the proceedings lasted until 9. He suggested that in future the meetings should close at 8.30. This was agreed to.

Letter was read from Mr. W. Hlingworth, suggesting that the Photographic Press be invited to attend the Annual General Meeting to report its proceedings. After discussion the suggestion was put as a resolution and lost. Mr. R. N. Speaight raised the matter of the reports of meetings in the "British Journal." He thought the meetings should be more fully reported and in less formal style. He thought that the names of the movers and seconders of resolutions should be given, instancing that at the last meeting he had proposed a resolution, which was not adopted, that had not been reported. The Hon. Secretary replied that, with the duties he had to perform at the meetings, it was impossible for him to take notes, and that a full report of the proceedings was only possible if they had a shorthand reporter. It was not the duty of an hon. secretary

to report proceedings. He had been connected with ten or a dozen societies, and in every case there had been an official reporter or a member appointed to act as recorder, whose duty it was to record the proceedings and be responsible for them. In the early days they had a shorthand reporter, but even then lengthy reports were not often possible, as so much of the business consisted of matters still under consideration, which it would be inadvisable to publish in their immature state. If fuller reports were considered necessary there must be a shorthand reporter. After some discussion Mr. Lang Sims said he would bring his daughter, who was an efficient shorthand writer, to the next meeting.

Letter read from Mr. H. J. Rigden, auditor of the Association's accounts, criticising the way the balance sheet was made out and explaining how he thought it should be done. The Hon. Treasurer said that Mr. Rigden had raised his objection at the time of auditing the accounts, and that he, the hon. treasurer, had pointed out that the method adopted was that he had inherited from his predecessor. The balance sheet gave a clear indication of the financial position of the Association, which could mislead no one. There was something to be said for Mr. Rigden's contention from an accounting point of view, but it was only a matter of form.—After discussion it was agreed that no alteration should be made in the way the accounts were presented. The Hon. Treasurer stated that the February number of the P.P.A. Circular containing the notice of the Annual General Meeting, the Statement of Accounts, the attendances of members of Council, and the ballot paper was in print and would be sent out within the next few days. All members in suspense on account of army service would receive a copy. He also reported that he had arrived at a settlement with the Inland Revenue Authorities as to the amount of the Association's liability for income tax on its invested funds. Mr. R. N. Speaight called attention to a letter which had appeared in the correspondence columns of the "British Journal," signed by a member of Council, in which personal opinions were stated in such terms as to suggest they were opinions of the Council. He thought that members of Council in writing to the Press should be careful to make it clear that they were only expressing their own ideas, and should not refer to what had taken place at Council meetings.

A discussion was opened upon a paper of suggestions for the future conduct of the Association by Mr. Mason Adams; further consideration was deferred. Mr. Montague Cooper raised a technical point with regard to the proceedings at the January Special Council Meeting. The chairman read the rule and explained that the formality that Mr. Cooper stated had been omitted was unnecessary in the circumstances.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday February 25, Mr. E. W. Mellor, F.R.P.S., in the chair.

Mr. G. Avenell delivered a lecture, illustrated with lantern slides, on the West of England, his discourse taking the place of that by Mr. W. J. Roffey on "Some English Cathedrals," which had had to be unavoidably postponed. Mr. Avenell took his audience with him among many of the picturesque districts of Dorset and Devon, and had much that was interesting to say on the churches and other ecclesiastical foundations of the two counties. The scenery of Exmoor provided the opportunity for many attractive studies, and the lecturer introduced an eminently human element by showing a photograph of half a dozen girls on the heights of Dunkery Beacon and explaining that, despite his age and baldness, he had subsequently married one of them.

The hearty thanks of the meeting were accorded to the lecturer.

CROYDON CAMERA CLUB.

THE latest postcard circular states that "New gas fires are fitted to the club-room, which is now warm and comfortable," a fact which gives no suggestion of a terrible conflict waged between Mr. Sellors and the Croydon Gas Company as to whether the previous obsolete patterns should be discarded and up-to-date ones installed. Only when the officials of the company realised who they were up against, and that their persons were in danger of increasing in value by conversion into by-products, did capitulation occur. The immediate benefit arising from the change consisted in the frost breaking up as a matter of course; so balmy, comparatively speaking, was the atmo-

sphere last week that even Dr. Knott abandoned his usual sane habit of posing as a fire-screen.

Recently the syllabus has admirably indicated fixtures in which a lecturer down for any particular evening, will almost infallibly not turn up on the date assigned him. By any weird chance if the two do happen to coincide, the topic announced, and that actually dealt with, frequently will be hardly on speaking terms. It must be clearly understood, for he has so stated, this is not the fault of the secretary, who obviously must be the victim of a wicked and widespread conspiracy among lecturers to lead him astray. Bitterly he has declared that he washes his hands of them so far as relates to dates and titles.

Last week Mr. B. J. Rose, billed for a future date, kindly filled a breach caused by that wretched "flu," and crystallised two informal summer demonstrations into one coruscating evening on "Pinhole Photography." No member of the club has a firmer foothold on pinholes than Mr. Rose, and the wonderful definition he obtains is highly interesting. Interesting also were the simple box cameras, enlargers, and stereo-cameras shown, and also a pinhole stereoscope; a few, however, failed to coalesce the pictures with the last.

The lecturer's latest method of making the pinhole is as follows:—A piece of thin sheet brass, or the portion of the inner cover of a cigarette tin, is placed on a slab of lead, and a 1/4th ball bearing (or thereabouts), moistened for adhesion, is placed on top and given a slight tap with a light hammer. This gives a perfect half-spherical dent, the convex side of which is now rubbed down with a slip stone. The dent is centrally pierced on the concave side with the point of the needle, and further rubbed down, these operations being repeated several times until the hole can be traversed by the needle almost up to its head. If on the first insertion of the needle the metal breaks away irregularly, too much has been taken off by the stone, and the piece should be discarded. For normal extensions on a quarter-plate a No. 9 needle, about 1/50th inch in diameter will, he said, be found very suitable.

The pinhole is mounted convex side towards the plate, and can be blackened with india-ink and a trace of gum. As a matter of fact all the prints shown were from negatives taken with unblackened pinholes. Although this apparently had no injurious effect on definition, yet blackening appears desirable, as a glittering edge might cause general fog over the plate, and possibly markings by reflection of bright objects. One or two prints did show markings, not unlike "flare."

An animated discussion followed the lecture, the many questions asked showing the interest taken in the subject. In reference to some square "pinholes" of novel construction shown by Mr. Rose, Mr. A. F. Catharine gravely pointed out that their shape should entirely eliminate spherical aberration. It sounded sense, and many members looked duly impressed; it was a pity that others laughed and gave the show away. A most hearty vote of thanks was accorded for a demonstration of unusually complete character, one which must have entailed a lot of preparation.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—At the last meeting Mr. W. F. Slater gave a demonstration of Velox and Transfer-type printing. Mr. Slater introduced his subject by stating that a gas-light paper is a development paper which can be safely handled in gaslight, and did not necessarily mean a paper to be printed by gas-light. Soft Velox was 1/60th the speed of Kodak bromide, and vigorous Velox 1/3rd the speed of the soft grade. Because negatives varied in contrast it was necessary to use varying speeds of papers, and as contrast was governed by development, the makers of soft and vigorous grades of papers supplied a means whereby errors in development in the negative could be partially rectified in the print. Vigorous Velox for soft negatives and Soft for vigorous was recommended. The grade of paper to be used was governed by the contrast of the negative, not by density. A glass-backed printing frame was a great aid where shading had to be done, as one could look through the paper and see the portions requiring treatment. Exposing by magnesium ribbon was demonstrated, it being pointed out that the amount burnt should be kept to one fixed standard, and the distance varied according to the density of the negative; but when printing, and using the ordinary household gaslight, it was advisable to vary the time of exposure, and to keep the frame at one fixed distance, for preference on a box, face upwards, directly under the light. There

is no such thing as over-development of gaslight or bromide papers: if the resulting print is too dark, it merely points to over-exposure; if too light, under-exposure. Development to finality was strongly recommended, and demonstrated by the following test:—An exposure on Velox was made, and one-half of the paper immersed in the developer for about two minutes; the other half was then slipped in until the whole print was immersed, and development continued until no join was seen. This constituted finality in development, and from a print treated in this manner the exposure could be correctly judged: in fact, this was the only reliable test. To avoid stains the print must be rinsed between the development and fixing, and kept well covered by the latter. To remove stains a bath of hypo and ferrocyanide was to be used. Rich sepia tones could be obtained on Velox if the development was full and the print was first placed in the toning bath, then transferred to the reducer, and again placed in the toning bath. Mr. Slater demonstrated the transferring of Transferotype to plain glass, upal, and single transfer paper.

Commercial & Legal Intelligence.

LEGAL NOTICES.—Notice is given of the dissolution of the partnership between Mark Heron and Abraham Wechsler, carrying on business as enlargers and artists, at 67, Great Ducie Street, Manchester, under the style of the Central Art Studios. All debts due to and owing by the late firm will be received and paid by Mark Heron.

NEW COMPANIES.

LOCAL VIEWS, LTD.—This private company was registered on Feb. 17 with a capital of £5,000 in £1 shares. Objects: Printers, engravers, publishers, book, postcard and print producers, photographers, etc. First directors: J. F. J. Grimm, 4, Adys Lane, St. Paul's Avenue, Cricklewood, N.W.2, printer, and H. V. Woodward, 43, Chiswell Road, S.W.16, printer. Registered office: 9, Goswell Road, E.C.

BRITISH ILLUSTRATIONS, LTD.—This private company was registered on February 19 with a capital of £5,000 in £1 shares. Objects: To take over the business of press photography carried on by S. E. K. Richardson at 4, Johnson's Court, E.C., as the "News Illustrations Co., Ltd." The subscribers (each with one share) are: S. E. K. Richardson, 50, Rowland Road, Balham, S.W.17, journalist, and J. W. Parker, Athlone, Granville Road, S.W.18, journalist and photographer. First directors: S. E. K. Richardson (permanent), J. W. Parker, and W. W. Gee. Registered office: 4, Johnson's Court, Foot Street, E.C.

News and Notes.

Messrs. LITHWELL, LTD. inform us that they have now got back a sufficient number of men into their trade printing department to justify their drawing the attention of photographers to it as they do in an advertisement in another page of this issue.

ARGO FRAMES. A correspondent would like to discover the address of the maker of gilt metal frames issued as "Argo" or "Arco," and believed to originate in Birmingham. If any of our readers have the information they would oblige our correspondent by communicating with "Argo," care of the Editors.

DREAM PORTRAITS. Many readers having at one time or another written to ask how to make the combination photograph in which a second portrait is vignettted into one of a sitter, it may be of interest to state that the work is a speciality of a firm of trade workers, Army and Navy Studios, Aldershot, by whom the necessary composites are made from any two portraits.

PRESS PHOTOGRAPHIC AGENCY.—We are glad to be able to say that the joint proprietors, Messrs. Harold Outram and G. W. Lymbery, of this agency for placing photographs with the Press, are now returned to their business after a fairly long spell in the

Service. As one of the smaller agencies in which individual attention is given to clients' commissions they will, we are sure, speedily regain the custom from photographers which has been interrupted by their absence in the Army.

THIOCARBAMIDE. The British Drug Houses, Ltd., 22 30, Graham Street, London, N.1, writes:—"Our attention has been called to a statement in the BRITISH JOURNAL OF PHOTOGRAPHY of February 14, 1919, page 80, under the heading 'Bleach for Bromides,' to the effect that thiocarbamide is a German product, and is now unobtainable. We beg to be allowed to correct this statement, and to inform your inquirer that we have manufactured thiocarbamide in our laboratories for several years past, and we are now able to supply any reasonable quantity from stock."

DARK-ROOM ILLUMINATION.—In reprinting in "Camera Craft" the article on the fitting-up of the dark-room from our issue of August 30, 1918, Dr. D'Arcy Power, of the staff of our San Francisco contemporary, describes his own method of dark-room illumination, which it will be seen is of a kind which we have often advised but which nevertheless obtains an added recommendation in coming from so practised a writer. Dr. Power writes:—

For many years I have employed indirect illumination in my dark-room, in which I am constantly developing plates of high sensibility, always orthochromatic, and frequently panchromatic. While I always have an abundance of light, I think I can safely say that my negatives are free from any signs of fog. The method that I have employed is one that can be carried out with the greatest of ease, costs but little and gives results which only need to be experienced in order to be appreciated, and I use direct light only for the momentary examination of plates. Over the full length of my developing table is a shelf, its back edge fitted close to the wall, light-tight at point of contact, this shelf inclining, directed upwards at an angle of about sixty-five or seventy degrees. This shelf is simply a ten-inch plank, although it might be better to have it a little deeper. Its upper or inner side is painted white and the walls of the room are light coloured, a light red, although I believe a yellow tint would be preferable. On the inside of the trough formed by the shelf are four electric bulbs, one dark green, and the fourth an open white light, operated by switch buttons on the outer side. In general, the red is used for plate work, the yellow for bromide paper, the green occasionally for panchromatic work, and the white, of course, for general illumination. The light falling on the inclined surface of the shelf is reflected upwards to the walls and ceiling, from which it is again reflected, illuminating the room to such an extent that with only the red light turned on it is quite possible to see everything in the room with ease and comfort, even to reading the labels without difficulty, and I have never found this indirect light to cause fog on a plate. I rarely use any other light for determining when my development is completed; but, if it be thought necessary to do so, I can employ direct light. Opposite each of the four lights is an opening in the shelf, these closed by a piece of groundglass on the inside, and a dark slide on the outside. This enables me, by simply drawing the desired dark side, to make use of direct transmitted light for the momentary examination of the plate. In my own practice I rarely find need for this provision, but I realise that in some cases, such as in X-ray plate development, there is a real need for the use of direct illumination. I have not only used this method myself for many years, but I introduced it to the notice of one of our leading local radiographers, whose daily work is quite heavy, and he is loud in its praise. I sincerely hope that any photographer re-building his dark-room will try this method of lighting, doing so with the full assurance that he will never think of using anything else.

FORTHCOMING EXHIBITIONS.

February 22 to March 8.—Edinburgh Photographic Society.
Secretary, George Massie, 10, Hart Street, Edinburgh.

April 17 to May 22.—Hammersmith Hampshire House Photographic Society Annual Exhibition. Two open classes. Entries close March 13. Joint secretaries, J. G. Abrahams, 41, Hamilton Terrace, London, N.W.8; A. H. Page, 12, Lime Grove, London, W.12.

Correspondence.

AERIAL CAMERAS.

To the Editors.

Gentlemen,—As one who is deeply interested in aerial photography, and who knows the capabilities of the R.A.F. cameras (which are second to none), I regret to think that it is possible that such an article as the "Future of Aeroplane Photography" could appear in our leading photographic journal. Yet, perhaps, it is just as well that it has been published; it will wake up the powers that be, so that the British public may learn what great strides have been made in aerial photography.

Mr. Holst may be a designer and instructor of aerial cameras, but he should not make definite and sweeping statements about cameras of which he could possibly know nothing, the design and make of the R.A.F. cameras being secret. Suffice it to say that Mr. Colin Williamson's automatic and semi-automatic aerial cameras are years in advance of the camera mentioned in this article.

The Williamson "Aerocam" not only does what the inventor of the Brock camera claims, but much more, and it was doing it in 1915. Since then things have moved very rapidly.

Hoping you will give this letter publicity, I enclose my card.—
Yours faithfully,

ONE WHO KNOWS.

February 22, 1919.

To the Editors.

Gentlemen,—The most interesting article appearing in your issue of the 21st inst., under the above heading, whilst doing full justice to the particular camera designed by the authors, is, in my opinion, grossly unfair in that it ignores the existence of similar apparatus which was in use long before the "Brock."

Certain sweeping assertions such as "the mapping use of aeroplane photography has been to a certain extent set back by the war, photographic apparatus . . . adapted to this class of work. . . . excludes . . . any instrument rigidly attached to the aeroplane, surveying work must be obtained by an automatic camera," ought not to pass unchallenged. However, the technical authorities of the Air Ministry Photographic Section could no doubt provide interesting data on these points, with more authority on the matter than myself.

Messrs. Brock and Holst may be surprised to hear that fully automatic cameras were in use by the Royal Flying Corps in 1915, and that these cameras had a far greater scope than that claimed for the "Brock." The standard film used was 4-inch wide and the photograph 5-inch long. 250 exposures could be made with one loading, and as this could be accomplished in daylight, in the air, the ground covered was practically unlimited. The whole action of the camera was automatic, each photograph registering the height and direction of flight through a separate lens. Timing the exposures could be made at the will of the pilot to suit varying heights and speeds from 0.5 fraction of a second. The power was derived from an air vane with patent speed controlling device and varying methods of suspension were used, from air cushions to gyroscopic gimbal cradles, so that Brock's claim that "no other camera has been built with a system of free suspension" will not stand investigation. As to the designs of the majority of the automatic cameras used during the war by the Royal Flying Corps, I think I can speak with some authority, but I should be glad to see a reply to the article above mentioned from those who informed me that my "automatic cameras were invaluable in the Mesopotamia and Palestine campaigns, where large tracts of land were successfully mapped, without the aid of Brock and Holst.—Yours faithfully,

COLIN M. WILLIAMSON.

23, Denmark Street, Charing Cross Road,
London, W.C.2.

February 25.

AVOIDING DEVELOPER POISONING.

To the Editors.

Gentlemen,—I notice a lot of photographers suffer through metal poisoning. When I started with M. Q. about twenty years ago I suffered in the same way. I liked the developer better than any other, so I put on my thinking cap and the result was I bought a pair of forceps, flat ones. They are difficult to get now—and were then—so I took two brass pressure bars off an old half-plate printing frame and cut them a little, and bolted the ends with two bolts, taking good care to see that the end I was going to use was quite smooth. In making a bromide print, I lift the end of the dish up, put the print in, and flow over the developer. With the forceps I then take hold of the side or corner of the print and turn it over and over until finished, or leave it in the dish, rocking it, until it is finished. I then pick it up with the forceps and put it into a fixing-clearing bath of sulphite, acetic acid, alum, and hypo, keep it moving with another pair of xylonite forceps or a paddle. I do not touch the print with my fingers, and therefore do not have to wash my hands after every print.

After making the trial, I print, say, a dozen and put them one after the other into the developer, each one at the bottom. When finished I take them out with the forceps and carry on as before. Many travellers who have called on me when I have been at work say it is the easiest way of working they have seen, and for a one-man business quite the thing. I even use them for sizes up to 12 x 10, but for a larger size it is necessary to use the fingers, in which case I dip them in water first and take care not to keep them in the developer longer than is necessary. I have never suffered since, and as I do not have to keep washing the hands I am able to turn out a great quantity of work.—Yours faithfully,

A. ENGLAND

50, High Street, Barnes

THE WORD "BIOSCOPE."

To the Editors.

Gentlemen,—I am much interested in the "cine-kine" controversy in your pages. I have always been a "cine" man, and admired Mr. Lockett's letter in support of it; but "Kino," whose letter appears on page 90 of your last week's issue, appears to have given "cine" a knock-out blow.

Arising out of the "cine-kine" affair is the word "bioscope," which your correspondent tells us became "an English name in 1894." It may have found its way into the archives of the Patent Office in that year, but the word itself is of an earlier date. It appears, for instance, in the supplementary volume of Knight's "Dictionary of Mechanics," a volume published in 1884—ten years earlier than the date given by your correspondent.

The bioscope of 1884, however, was not the motion-picture instrument we know to-day, but, in a way, closely related to it. It is thus described: "A double-vision instrument. In a recent invention of M. Eugène Simonar, a portrait is shown with the eyes sometimes open, sometimes shut. The illusion of the same person alternately awake and asleep is very perfect. To obtain this effect, the inventor takes a double photograph of a sitter in exactly the same position, only in the first the eyes are open, in the second closed. From these two negatives prints are taken, one on the right side, the other on the reversed side of the same sheet of paper, in such a way that the two images, when viewed by transmitted light, accurately coincide; this can be easily done by the carbon process. By means of a small instrument arranged for the purpose, the light and reversed sides of the paper are alternately illuminated, and the face is seen with the eyes successively open and shut." Thus the bioscope of 1884 is of particular interest.

When the word bioscope was applied to motion pictures of the cinematograph type, or rather a machine for exhibiting them, some of us took it to be a simplification of the word "biophantoscope," the name given to a moving picture instrument introduced by a Mr. J. A. Rudge, of Bath, in, or about, the year 1870. This instrument, which is usually overlooked by historians, was a projection machine on the same principle as the modern instrument, except that the movement was horizontal; a circular band of lantern slides was made to revolve around a stationary lantern.—Yours faithfully,

L. TENNANT WOODS.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

D. H.—Paper ready coated for the gum-bichromate process is not obtainable.

L. S.—Write to the Registrar of Business Names, 59, Russell Square, London, W.C.1.

F. M.—So far as we know there is no objection whatever to your styling yourself "army photographer."

S. P.—Messrs. Hood and Co., Limited, of Sanbride Works, Middlesbrough, supply bronze memorial tablets.

K. E.—Messrs. W. Butcher and Sons, Limited, Camera House, Farringdon Avenue, E.C., supply fasteners for affixing photographs to mounts.

W. W.—You need be under no apprehension as regards the effect of the mercury-vapour light on your eye-sight. No harm at all will result.

G. W.—There are perhaps a hundred different patterns of between-lens shutters, and the mechanism in each varies more or less. You can surely form some idea by watching your own shutter work.

N. E.—It is a nice point, but we should say that ninety-nine photographers out of a hundred would think there was nothing inconsistent in placing their name on a work produced as you describe.

E. W.—It is very likely that the defect is caused by the impure spirit. We advise trying "pure spirits of wine" from the chemists, which, though a good deal more expensive, should be worth its extra cost.

I. R.—The films are sold to go into ordinary dark-slides with a cardboard backing in the manner of the flat film which was much in use some years ago. If you write to the Kodak Company, King'sway, London, W.C.2, they will send you every particular.

W. P.—In previous years admission has been by invitation of the Board of Trade only, but there is no reason why you should not apply for tickets to the address as follows:—Board of Trade, (British Industries Fair), 10, Basinghall Street, London, E.C.2.

B. F.—We wish we could oblige you with the information, but unfortunately we have absolutely no data. So far as we know, it is not possible to quote figures which will be in any way a reliable indication of the minimum quantity of developer or hypo which can serve for prints.

C. J.—The firms who buy old negatives for resale of the glass, clean off the films by dipping in a nearly boiling solution of caustic soda. This removes the film almost instantaneously, but it is bad for the glass, and causes, with some types of glass, a matting effect. Another plan, which we believe is free from this objection, is to allow the negatives to soak for some hours in fairly strong nitric acid.

W. E.—Messrs. H. T. Heron and Co., 10-11, Tottenham Street, Tottenham Court Road, London, W.C.2, price 5s. 6d. Mr. W. Heinemann, 21, Bedford Street, W.C., price 6s. The "Modern Bioscope Operator" (Messrs. Ganes, Ltd., 85, Shaftesbury Avenue,

London, W.C.), does not deal with the making and developing of film, but with its projection and illumination and methods of electrical installation.

J. N.—The formula is intended for gelatine ferrotype plates, and for cards coated with a similar emulsion. There are no books on ferrotype photography, and we have no information on the making of positive cards. These goods came for the most part from America, and the knowledge of the emulsions is in the hands, we should say, of only one or two people.

C. A.—(1) Several series of books, the publishers of which we do not know, but you can get them at any good booksellers; also the Medici Society, of Grafton Street, Old Bond Street, London, W. (2) We do not know of any text-book which particularises subjects. (3) We should think anyone who is able to use a saw and hammer could make such a stretcher with very little trouble.

W. D.—(1) The American writer was no doubt referring to an American article. We know of no one in this country who coats what is presumably Japanese vellum with bromide emulsion. (2) We are afraid you will have difficulty in removing the red-ink titles. The only suggestion we can make is that you paint the portion of the negative with a fairly strong solution of hydrochloric acid and then wash well in plenty of water.

E. B.—The arrangement seems quite good so far as the electric light goes—have the light as high as you can manage, certainly 8 ft. from floor, for standing figures, and lower it for sitting ones and children. If the window is only 6 ft. high from the floor, it will be useless for full lengths, but will do for heads. If it goes nearly to the ceiling it will be all right. It is very desirable to have the background easily movable, so that you can get variety in your lighting by moving the sitter and camera to obtain the proper effects.

G. W.—Most lenses in sunk mounts are made so that the diaphragm is rotated by a milled ring on the front of the lens hood, and therefore the latter is not available for the support of a cap or shutter. Such lenses are almost invariably employed with a focal-plane shutter, but no doubt you could get made a fitting which could be attached to the lens partly, and would be fitted forwards clear of the diaphragm ring. It would be clumsy, but still practicable. For a mirror or other fittings for a reflex camera you should apply to a firm of camera repairers, such as Messrs. H. T. Ball and Co., 51, Berwick Street, Oxford Street, W.1.

S. F.—It is impossible to say what weight of hypo is contained in a saturated solution at a given temperature. The solubility of hypo varies so considerably for a degree difference in temperature that such methods of making up a saturated solution are not sufficiently accurate. Our own plan is to dissolve hypo at the rate of 1 oz. per 2 ozs. of solution, that is to say, we dissolve 1 lb. of hypo in hot water and make up to 32 ozs. water. This gives a solution which is sufficiently concentrated, and is easily measured out for making up fixing baths of various strengths, it being necessary simply to reckon two fluid ounces for one ounce of hypo.

S. C.—1. We should think the best book for your purpose is either "Varnish Materials," by J. G. McIntosh, price 10s. 6d., or "Analysis of Resins and Gum Resins," by Dieterich, price 7s. 6d., both published by Scott, Greenwood, 8, Broadway, Ludgate Hill, London, E.C. 2. These questions are rather out of our line, and the only advice we can give you is to apply to Messrs. Johnson and Sons, Ltd., 23, Cross Street, Finsbury, E.C., whom we have found exceedingly efficient in obtaining chemicals of all descriptions. 3. Not so easy to say, but we should think that chloral hydrate, which renders gelatine permanently soluble, could be used with reasonable chances of success.

M. Mc.—The following old method is perhaps what you want:—
 Water 160 ozs.
 Sugar of lead (lead acetate) 8 ozs.
 Hyposulphite of soda 8 ozs.

The solution is used as hot as possible, and the brass work is simply dipped in it, and allowed to remain until black. This takes about a minute or less. The articles are then rinsed in cold water, then in hot water, and dried. If scratch-brushed dry, the black deposit will have a high lustre. When dipped into the solution, the surface of the brass article becomes yellow, then blue, and

finally black. The article should not be taken out until all the surface has become blackened. The deposit on it is sulphide of lead. The articles should always be lacquered, otherwise the black deposit is likely to oxidise and fade; but if coated with lacquer, it seems to be quite permanent.

A. G.—We think you may safely construct the studio on the lines you mention, with one modification, which is, put more glass on the roof. You will then be able to keep your sitter well back and use the light at a considerable slant. If for structural reasons you cannot extend the area of the glass, it would certainly be desirable to raise the whole studio as high as possible, so as to minimise the effect of the outside wall. This wall, by the way, should be lime-washed, so as to reflect as much light as possible. Lime stands the weather better than distemper. We have recently been fitting up a studio with a wall similarly placed, and giving about the same angle of light, and it works quite well. In this case the side windows were stippled with very thin zinc white paint, and this seemed to improve the lighting considerably. With regard to the half-watt lamps, your proposed arrangement is quite good. Have four 1,000 c.p. lamps and a separate switch for each. You can then use only as many as needed. The blind arrangements and wall decorations will be quite right.

J. McD.—A process very similar to yours was patented in Germany in 1912 by E. Rickman. An improved silver-uranium printing paper was obtained by addition to the sensitiser of small proportions of thiocarbamide compounds and of haloid alkaline salts, such as ordinary sodium chloride (common salt). The more of this latter the solution contains, the greater the tendency of the finished print towards a yellowish-brown; the greater the proportion of thiocarbamide, the blacker the prints. The addition of these two substances to the silver-uranium sensitiser renders the paper non-liable to alteration of tone in patches when washing the finished prints. A specimen formula of the sensitiser is as follows:—

Uranium nitrate	25 gms.
Silver nitrate	9 gms.
Thiocarbamide solution, 1 : 205 cc.
Sodium Chloride, 1 : 1005 cc.
Water distilled	50 cc.

This sensitising mixture is applied to papers prepared with starch.

IMPORTANT NOTICE.—Advertisers are requested to notice that the prices printed below represent an

Increased Scale of Charges,

which is now in operation in respect to all line announcements.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind this revised tariff. They will thus save themselves delay in the publication of their announcements.

Net Prepaid Line Advertisements.

Increased Tariff of Charges.

12 words or less	1/-
Extra words	1d. per word.
(No reduction for a series.)	

Special Note. Adv'ts under a Box Number.

"Box No." and office address charged as 6 words.
 For forwarding replies add ... 6d. per insertion for each adv't.
 If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.
 Orders to repeat an adv't must be accompanied by the advertisement as previously printed.

Advertisements are not accepted over the telephone.
 The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.

Displayed Adv'ts should reach the Publishers Monday morning.
 The insertion of an Advertisement in any definite issue cannot be guaranteed.

SUMMARY.

The opportunities for commercial photography, which are foreshadowed in industrial development upon a large scale in this country, are briefly touched upon in a leading article on page 110.

In his article this week, "Practicus" deals with a number of practical points bearing on the heating and ventilation of studios. (P. 111.)

A contributor to the *Electrical Review* describes the use of the portable electric generating station, such as have been largely employed with the armies in the field, and provide a source of electric light for photographic studios situated in country places where neither gas nor current is available. (P. 113.)

An instrument for the measurement of focal length is the subject of a recent patent specification. (P. 116.)

A contributor to "Assistants' Notes" has a number of very well-considered hints to give on the preservation of the eyesight by those engaged in photographic work. (P. 115.)

We regret to announce the death at the age of thirty-five of Mr. H. Easenigh Corke, of Sevenoaks. (P. 115.)

Major Charles W. Gamble will read a paper on serial photography at the Optical Society on Thursday in next week. (P. 114.)

A photographic survey of London during the present year is contemplated by the Camera Club. The aims of the scheme are set forth on page 114.

The Lumière method of drying negatives with a saturated solution of potassium carbonate may on occasion usefully replace those employing methylated spirit or formaline. (P. 110.)

The advantageous use which can be made of a vest-pocket camera in commercial photography is instanced in a paragraph on page 109. In general the advantage of the vest-pocket camera is the combination of large aperture and depth of focus which it affords.

A couple of suggestions for business other than that of making photographs which might be added to a studio establishment are made in a paragraph on page 110.

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

Particulars are given of a process, patented by Mr. F. E. Ives, of producing colour transparencies from colour sensation negatives, and consisting in the formation of a composite of two-colour positives. (P. 9.)

The necessity of excluding dust from between the screen-plate and the emulsion in the Paget process is the subject of a practical paragraph on page 12, in which it is recommended to bind the two plates temporarily together.

In the present instalment of "Decennia Practica," particulars are given of two pseudo colour processes which in their day had some vogue. (P. 11.)

EX CATHEDRA.

Photographic Survey of London. The communication from the Camera Club, which we print upon another page, sets forth what is truly a very

ambitious programme, no less than a comprehensive survey, in the form of photographs, of London at the present time. Until the opportunity occurs of learning, from the booklet which is shortly to appear, the contemplated organisation of the undertaking it is clearly impossible to form an estimate even of its possibilities. But, at any rate, it may be thought that a scheme of which one first hears in March must call for an enormous and well-disciplined body of workers if it is to achieve its end of recording the face of London in the Peace year 1919. At the best of times it is difficult to stimulate an interest in the making of records which are to serve our descendants, and while we cannot too highly value the interest which the Camera Club is showing in this work, we are bound to think that some extraordinary army of photographers will need suddenly to be brought into existence if the aims of the promoters are to be realised.

The "Vest Pocket" Commercial Operators.

There are occasions when a high-grade small camera, far from being a toy, may be of very real service to the photographer placed in exceptional circumstances. The fact that these instruments are fitted with lenses of short focus and wide aperture, and thus give good definition over many varied planes of distance without recourse to stopping down may often be of real service. A case in illustration of this point was told to us some time ago by a commercial worker. He was commissioned to make a series of pictures in a factory, which was rather poorly lighted, of certain pieces of machinery. As the work would have necessitated the use of a lens well stopped down in order to gain the required definition, and as the stoppage of the machinery was an important factor the operator took with him a vest-pocket camera. This he found gave all the definition required, and fine definition without stopping down the lens. The result was that the pictures were taken in a very short time, as the worker was enabled to use the lens working at $f/6$ instead of one stopped down to $f/22$. Enlarged prints were made that gave the customer entire satisfaction. The same operator at a later period had to obtain a view of an old country house in the North of England for an estate agent, and the subject required could only be satisfactorily photographed from a narrow ledge of cliff about a foot or eighteen inches wide. This was obviously impossible with the field camera, but, not to be beaten, the operator took his vest-pocket camera, carefully worked his way to the spot, and then, holding on to a bough with one hand, operated his camera with the other, using the instrument at eye level. The

result was a new and striking picture that had a material value in selling the estate. Though, of course, not to be looked upon as a universal instrument, the modern vest-pocket camera fitted with a good anastigmat will often prove of very real value to the commercial operator when he is faced with difficult subjects. Provided care is given to obtaining a satisfactory negative there is no reason why, with a little working up, the resulting photographs should not be equal, and they may even be superior to contact prints from large negatives.

* * *

Non-photo-graphic Side Lines.

From one or two professional photographers during the past few days we have received letters asking for suggestions for other business, within the technical capacity of a studio establishment, which they might take up. While such enterprise has been undertaken, within our knowledge, by one or two photographers, it is difficult to make general suggestions, since very much will depend not only upon individual craftsmanship but upon the local demand for such articles of manufacture as may be produced. However, it may be worth while to mention the instance of a firm of Scottish photographers who have taken up, we believe with considerable success, the designing and making of toys, whilst in Kent is to be found a photographer who has specialised in the manufacture and design of fancy leather goods, such as calendars, and blotters, and whose work, as we have seen it at the British Industries Fair, possesses merit of a high order. It was first shown at the Fair of some two or three years ago, and as the exhibit is included also in this year's Fair it may be supposed that the project has turned out to be profitable.

* * *

Vignetting Bromides.

Those who have cause to complain of the hardness of outline of bromide prints exposed in one or other of the customary machines may be glad of one or two hints which, if taken, will go a very great way towards removing a defect of this kind. One is to cut the vignetting card from the corrugated board sold for packing. If the board be cut so as to give a bevel edge to the opening, the corrugations will provide a series of serrations which make for softness in the print. The second hint is to interpose a sheet of fine ground-glass midway between the vignetting card and the negative. Most printing machines will allow of a frame being inserted between the vignetter and the negative, so that the glass can be introduced in the required position without adjustment, and as quickly removed when unvignetted prints are required. The glass, of course, cuts down the light, but in these days when light of almost any power can be obtained from electric lamps this is a matter of small moment.

* * *

Drying Press Negatives.

A method of quickly obtaining negatives in a condition for printing and enlarging, which is less known than it deserves to be is that discovered some seven or eight years ago by MM. Lumière. It consists simply in soaking the washed negative for about five minutes in a saturated solution of potassium carbonate. The effect of this treatment, quite contrarily from what might be expected, is to produce a temporary condition of hardness of the gelatine film, permitting of the negative being rubbed dry with a clean, dry cloth, after which it can be immediately printed from or enlarged. The readiness with which a negative is obtained in this state requires to be the subject of trial before it can be appreciated. On taking out of the carbonate solution the film seems to be covered with a film of grease, but is very quickly polished with a cloth. We should not care

to keep negatives in this condition if value is attached to them, for obviously, in the case of retention of such a hygroscopic salt as potassium carbonate, the film must remain moist, and such a condition is bound to aggravate any causes of impermanence which may arise from imperfect fixation. Moreover, we have come across plates which showed a tendency to strip from the glass under this treatment, and, therefore, on both accounts the negatives should be washed for a few minutes and dried in the usual way as soon as their immediate purpose has been fulfilled.

RECONSTRUCTION AND PHOTOGRAPHY.

EVER since victory was assured to the Allies the word reconstruction has been upon our lips. Some very wise folk may know what it means when applied to the British Empire, or, perhaps, it would be more accurate to say, the United Kingdom, but to the majority of us it simply means getting back into working order, with better conditions for the workers and upon a firm basis all round. There is, we believe, a general determination to bar the importation of German and Austrian goods into the country, either by legislative or voluntary means, and we trust that our readers will support this action in every way possible, taking care not to be deluded into purchasing goods made by German labour in factories started with German capital in neutral countries.

To supply the needs of this country we shall either have to import from our Allies or make the goods ourselves, and as Germany and Austria dumped vast quantities of finished work upon us, the question is whether the United States and Japan are to reap all the commercial benefits of the war, or whether we shall retain a fair proportion for ourselves. We believe in our manufacturers' resources to attain the second alternative, and this means an enormous stimulus to industry provided that wages are not forced to such a height that it is impossible to make a reasonable profit.

We may, therefore, look for considerable activity in the designing and building of factories, with all the necessary appurtenances of workers' dwellings, railway sidings, canal basins, and the like. With all this activity there must be much work for photographers if they are only alert enough to seek it, and to show that they are properly equipped for its execution. Otherwise the photography will have perforce to be done either by firms from a distance or by the direct employment of an operator who uses apparatus provided by his employers. The average photographer is rather apt to overlook the value of this commercial work, his experience of which is often confined to a few interior and exterior views of factories, with results which from want of practice have not been of the best. If he would realise that it is worth while investing in good and suitable apparatus and to learn how to use it he would soon be amply repaid; in fact, more than once the first job has paid for the camera and lens, and left a handsome balance. The greatest mistake that any business man can make is to sit down and wait for business to come to him, and with the photographer, this is especially so if he wishes to undertake commercial work. Orders for portraits may be secured by a good window show, but orders for factory work must be solicited. Provided that a reliable man can be obtained the photographer can gain much valuable time by employing a canvasser, or, as we should prefer to say, a traveller. Such a man need not be exclusively retained, and it is often easier for a traveller who already calls on a firm for, say, lubricating oils, to broach the subject of photography and secure an inspection of his specimens. Of course, he must be paid, but, as a rule, the greater portion of his remuneration is paid as commission, and is contingent upon orders being obtained.

The great point to be observed when dealing with commercial work is regularity and promptness. If a contract has been made to supply a weekly record of the progress of a building, the operator must be on the spot to the minute on the appointed day, and the prints must be delivered with equal promptness. If these have to be sent to the board of directors in London or Glasgow by the engineer in charge so that payment for work done may be made, no excuses will be accepted if they are not forthcoming, and the result will be the installation of a staff photographer, and the consequent loss of business and prestige to the photographer.

Besides the class of work we have indicated there are many others to be anticipated in the near future. We are told that land surveying will in the future be largely assisted by the employment of aeroplane photographs. The development and enlarging of these should come into the hands of the local photographer, and as more care and exactness are required for these than for ordinary work, remunerative prices should easily be obtained. The reproduction of plans on original, enlarged, or reduced scales, and the photography of complete machines and parts also come into the same category, while the opportunity of securing subjects which can be sold to the newspapers must not be lost sight of. If there is to be a visit of inspection, portraits and groups of interest and value may be

secured. Many papers are glad to give a standing order for such pictures to a reputable photographer.

Housing schemes should provide much work, and it should be impressed upon those engaged in them that there is no better selling force than a good photograph of a fairly large size, either in the form of original prints or as half-tone reproductions. It should be impressed upon estate agents or owners that the public will take a good "real" photograph upon trust, while they are apt to be sceptical over gaudy lithographs of proposed "happy homes."

Prices should not be cut too low, but at the same time should be calculated upon a strictly commercial basis, not forgetting to include a proper proportion of rent, rates, and taxes, and other overhead expenses. And it would be well if the district associations of photographers could agree upon a minimum rate for commercial work. In the past, even with cheap plates and paper, such poor prices were often obtained that it was doubtful if any real profit was obtained. We can now withdraw all these old price lists, and on the just plea of increased cost of labour and material issue more satisfactory ones. It is essential that good faith should be observed, and that no secret discounts or allowances be made to secure orders. In fact, let us have reconstruction all round, even in the business morality of photography.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
The Camera and the Lens (Jan. 10).
Managing the Sitter (Jan. 24).
Backgrounds (Jan. 24).
Studio Exposures (Jan. 31).

Artificial Lighting (Feb. 7).
Printing Processes for Portraiture (Feb. 14).
Studio Accessories and Furniture (Feb. 21).
The Surroundings of the Studio (Feb. 28).

STUDIO HEATING AND VENTILATION.

THE warming and ventilating of studios is a problem which has to be solved in many ways, these being dependent upon the construction, size, and position of the building, and the means of the owner, for it is obvious that what will suffice for the small "portable" type of erection will be inadequate for the large, solidly-built apartments in which the more fortunate among us are able to work. There are, nevertheless, certain general principles which must be observed, no matter what be the size or design, and the owner of the little studio should carefully consider what he can best do with the sum appropriated to the purpose before parting with it. Among these I would put evenness of temperature, cleanliness, freedom from injurious fumes, and economy of fuel, the latter being likely to be more important in the future than it has been in the past.

The position of the heating apparatus should be carefully chosen, as much depends upon it, and, above all, the error usually made by builders of dwelling houses should be avoided—that of placing the stove at the end of the room opposite the door, in which position it creates a draught of cold air and only warms a limited area, giving rise to the complaint that one is frozen on one side and roasted on the other. In warming a studio it is desirable that the stove or radiator should be placed near the door so that the air is warmed in its passage into the room. In studios which have a glass roof—and these are still in the majority—the stove should be placed under the glass, as near to the side light as possible, as not only is this the coldest side by reason of there being only one thickness of glass as a

barrier to the outside temperature, but that the warm air ascending to the roof may melt any snow which may fall upon it. I have often known work to be stopped by a thick layer of snow on the glass, and in attempting to remove this by mechanical means the glass may be broken, an unpleasant state of things in midwinter.

With regard to the heating apparatus, there is a wide choice ranging from a boiler and steam or hot water pipes to a portable oil stove, and each has its advantages and drawbacks. On the whole, I have found hot pipes the most satisfactory way of heating, and these, if possible, should be run the whole length of the studio close under the side light, a shelf or flat piece of wood should be placed above them, and the front should be screened with wirework (as ornamental as may be), fixed on frames which can be easily removed when the pipes require attention. This screening hides the unsightly appearance of the pipes and does not interfere with the heating; in fact, the top strip or shelf serves to distribute the warm air more evenly. If the pipes are left exposed they must be painted, and it is important that oil paint should be avoided, not only will it emit an abominable odour when it is heated, but it rapidly darkens and becomes unsightly. Although a dark colour is the better radiator of heat, I consider that on the whole a paint made of finely-ground aluminium in celluloid, which is sold for the purpose, to be the best coating. If any other colour than silver be required to match the walls, a useful paint may be made by grinding powder colours of the desired shade in beer, stout for

preference. I have not tried Government ale for this or any other purpose, but I fear that its adhesive properties would be too poor. This beer colour is used for painting the funnels of steamers, which get rather hotter than the average steam or hot water pipes. It must not be thought that such an installation is a very costly affair if the existing types as used in greenhouses are selected. They may be had in all sizes, and the makers will estimate for the complete outfit if the cubic contents in the studio in feet are given, with the temperature it is desired to obtain. It is necessary to point out that in severe weather the fire must be kept going night and day, not only that the studio may never be allowed to become cold, but to prevent the water freezing and causing fracture of the pipes or an explosion of the boiler.

A useful modification of this system is to have separate radiators, each of which is filled with water heated by an atmospheric gas burner. I know of several studios where they are giving every satisfaction, although a reduction of the gas pressure sometimes lowers the heat to an undesirable extent; to minimise the risk of this the supply pipe should be of ample proportions. A large pipe does not imply a large consumption of gas, but it secures an adequate supply when the pressure is low. When using this or any other system in which gas is burned in the studio, efficient ventilation must be arranged for, or the fumes will cause lassitude and even illness. For small studios one or more of the well-known siphon stoves may be used with advantage. In these there is a large central Argand burner flanked by two metal pipes which not only serve as radiators but condense the products of combustion into a liquid form. These stoves are economical in use and have a cheerful appearance. Two would probably be sufficient for a 20 by 12 studio. Open gas fires are cheerful looking, but rather costly for continuous use; they have also the disadvantage that unless well fenced in there is danger of clothing and drapery being set on fire, a danger which is also present with open coal fires, and one not to be ignored when children are about.

Closed stoves for coal, coke, and anthracite are very useful in the studio, but most of them necessitate either a brick chimney or an unsightly stove pipe. Of this group, those burning anthracite are the most desirable, as once started they will burn continuously for months if supplied with fuel. Thus the studio does not get cold during the night, and there is no trouble of fire laying each morning; all that has to be done is to empty the ashpan occasionally. The older type of slow combustion stove known as the "Tortoise" burns coal, coke, or cinders, and may also be kept continuously burning. Although this may seem wasteful it is really not so, for there is no necessity to make up a big fire every morning to warm the place up in a reasonable time, while the wood, paper, and labour required for lighting are saved.

In certain circumstances oil stoves are the only possible heaters available, and if a good pattern be chosen they are not to be despised. The tall, cylindrical pattern, with a bail handle by which it can be moved about, are very convenient, and if kept clean, is fairly free from the odour of the oil. The Salamander, or blue flame stoves, are very effective, but they are mean looking and cannot be shown in a well-appointed studio. I have, however, used one of these in a fancy cast-iron stove made for gas, and found it quite satisfactory. I have also found that one of these placed under the darkroom sink rapidly raised the room to summer temperature, the sink itself being warm, while the solutions were easily brought to normal temperature by placing the bottles near the lamp. If it be possible, when fitting hot water pipes, to run a bend into the darkroom, it is, of course, better in every way than an independent stove.

From heating the studio to keeping it cool is but a step, and in most people's minds keeping cool and ventilation mean the same thing. This is hardly so, for a studio can be perfectly ventilated and yet kept at a high temperature—it may be filled with foul air at a low one. The essential point in ventilation is to have the outlets and inlets for air properly proportioned and placed in such positions that straight-through currents from one to the other cannot be produced. In single-slant and other studios which approximate to an ordinary room the ventilation can be provided for by opening windows if in convenient positions, or Tobin tubes may be provided as air inlets; as a rule, the inlet should be fairly low and the outlets high. The Tobin tubes, which admit air in such a way that no draught is caused, are of the simplest construction, being nothing more than long, flat boxes of wood or metal, say, ten inches by three, in section, and about four feet in height. They are placed flat against the wall, and at the bottom have an opening to the outer air equal in area to their own inside sectional area, with a protective grating. The top, inside the room, is left open, so that the air on entering has a tendency to rise and becomes evenly distributed. Four such tubes are sufficient for a moderate sized studio. The outlets should be of the ordinary grating type, with mica flaps placed high in the walls, so that there is no accumulation of hot air in the roof. For very hot weather a large flap opening should be provided, as high as possible, at both ends of the studio, so as to permit of a free draught from end to end. It is necessary that the coverings should not permit light to enter above the backgrounds, and this can easily be done by fitting inside louvres after the style of a venetian blind. This is a better arrangement than having a lifting sash or trap-door, as is frequently seen, since the current is more perfect, and there is perfect protection against rain. Of course, there must be a hinged door or shutter inside or outside the louvres. This arrangement is supplementary to the small mica flap ventilators, which are sufficient in cold weather. Small electric fans are very useful for keeping the air in motion in very hot weather, but are not available in many places. The roof of a studio should always be double on the dark side, as this prevents heat from being radiated from the outer roof, which in a north-lighted studio has the full midday sun upon it. In positions where the sun strikes upon the glass it is a good plan to have a long iron pipe, perforated with small holes, running along the entire length of the glass. This is connected with the water supply, so that the glass can be flooded with a gentle stream which quickly evaporates and reduces the inside temperature to a considerable extent. It is also very useful for keeping the glass clean. A flood of cold water is harmful, as if turned suddenly upon hot glass it is liable to make the roof leaky if putty is used for glazing, as it is in the majority of cases.

Much may be done to give an appearance of coolness by the choice of suitable colours for the walls. Green or greenish grey looks much cooler than red or even buff, while ferns, palms, and other plants assist in producing the same impression. One of the most refreshing arrangements I have seen consisted of a passage opening from one end of the studio fitted as a rockery, with ferns and a trickle of water over the stones. Such surroundings produce a tranquil state of mind in the sitter and tend to the success of the portrait. I have also seen a side window opening on to a dingy mew, turned into a miniature rockery, with a tiny fountain with goldfish in a lake about two feet across at the bottom. These ideas may not accord with those of the "highbrow" artists of to-day, but they please the average sitter, and that is what we all strive to do.

PRACTICUS.

ELECTRICITY AND PHOTOGRAPHY IN WARFARE.

[The generation of electric current in places where no other source of light is freely available has of course during the active operations in France been an important branch not only of the Royal Air Force but of other sections of the army. Inasmuch as the use of such small installations are equally of interest to photographers in country places, we take the opportunity of reprinting from the "Electrical Review" an article describing the use of such units of equipment. Without an installation of this kind a photographer must fall back either on flashlight or on one of the incandescent paraffin lamps such as the Blanchard, neither of which can be said to rival a portable electric plant for all such portraiture as requires to be done by artificial light.—Eds., "B. J."]

Having recently returned from France, where I have been attached to a photographic section of H.M. Armies, it may be of general interest if I place on record a few particulars of the work of these sections, and the part played by electricity and engineering in carrying out their functions.

It must be clearly understood that these sections are not responsible for the actual taking of the photographs, as this duty falls on the Royal Air Force. The photographs cover quite a large range of subjects—such as front line and support trenches, panoramas of large tracts of country, large mosaics or photographic maps of certain parts of the country, "aerials" of particular spots, enemy gun emplacements, bridges and railways before and after bombardment, roads, etc.

The duty our little party had to perform was to turn out copies of these photographs in large numbers and very quick time, working, when necessary, night and day, to get the work turned out in time to be of service for the particular military operations they were required for—whether it was for operations on a large scale or for local raids or artillery work. To give some idea of the magnitude of the operations these small isolated and almost unknown "sections" of the Army carried out, I may say that work equal to 23,000 full-plate photographs was turned out in 36 hours for one of the big blows dealt at the enemy last August.

Having gone so far to show the extent of the work, we now come to the means of carrying it out, and this is where electricity and engineering played their part "in the game."

As these photographic sections have to move with the armies, the apparatus is often being dismantled, moved, and re-erected, and as the conditions vary with every move, retreating or advancing, the plant is put to work under a variety of conditions; sometimes the generating plant is resting on a few piles driven in the ground, and at other times on a good solid concrete foundation.

The plant I was in touch with consisted of one Gardner 5-H.P. petrol engine, direct-coupled to a 3-kw. Holmes generator running at 500 R.P.M. These machines were, of course, mounted on one bedplate. A second set consisted of a Petter Junior petrol engine, direct-coupled to a 3-kw. Holmes dynamo running at 725 R.P.M., on a common bed-plate.

The working voltage in the depôt was 110, and as a steady light was very essential for the photographic work on account of the time for exposure, for printing, equalising, etc., the supply to the depôt was always taken from accumulators, of which we had two complete batteries, which were used alternately, one being charged whilst the other set was being re-charged.

These batteries were generally accommodated in a room or hut near the engine-room, and complete control of the whole installation was obtained by a switchboard in the engine-room, fitted with the usual meters, charge and discharge switches, change-over switches for switching in or out either generator on to either battery, and also for switching either battery on to the works.

All outgoing circuits were controlled by switches and fuses on the main switchboard, and mercury vapour lamps, general lighting and night-light circuits, etc., were all separate.

The batteries were put up in oak boxes, lead-lined, and

fitted with lids, and each set had a capacity of 180 ampere-hours. These had a fair amount of rough usage during the various hurried removals, but kept up to their work very well.

As photographic prints of each subject were sent to our works, and not the original negatives, it was necessary to make a fresh negative from each print sent in, and this often meant over 100 subjects per day. These were taken with the aid of Cooper Hewitt mercury vapour lamps, two tubes in series in one frame, and two complete sets being used. In the case of photographs requiring to be enlarged, a Westminster arc lamp and enlarging camera were utilised. All printing from negatives was done in special printing boxes, lighted either by half-

Gardner Petrol Engine.

watt or ordinary M.F. lamps, and the same remark applies to the equalising boxes.

After being printed, developed, fixed, and washed, all prints were hung up in a drying-room heated by slow-combustion stoves and spirit flares, and the air was kept moving with two 12-in. electric fans. As the temperature in this room was generally about 120 degs., the prints were dry and ready for the cutters in a very few minutes.

The water supply was generally obtained from a stream near which the works were always situated, and the water pumped up to a supply tank with a Pelapone pumping set consisting of a petrol engine driving a turbine pump by means of a V-shaped belt, the set being mounted on a wooden frame, and so arranged that when the pipes were disconnected, it could be picked up bodily and carried. The water supply tank was generally fixed on a wooden structure near the main shed or building, and the water supply to all the washing sinks was run in screwed iron pipes, although a quantity of hose pipe was used for connecting up to the pump and tank at various

times. The quantity of water used would be about 2,000 gallons per day.

Floats and indicators were used in and connected to the supply tank, and arranged with electrical contacts either to ring a bell or switch on a coloured light when the tank was either full or empty.

The general lighting of the depôt, which consisted of dark rooms, cutting-room, stores, office, engine, battery and pump rooms, dining room, billets, etc., was carried out with ordinary M.F. lamps, and the general wiring was carried out on the cleat system, this enabling dismantling and re-erecting to be carried out in a very short time; I have known the plant to be dismantled and taken across country thirty or forty miles, photographic work being resumed in something like 48 hours. This, of course, was with a good deal of very temporary work, but the "military machine" had to be kept going, and the work of making a fairly decent job of the general installation had to be done whilst the place was kept working; very often,

A NEW PHOTOGRAPHIC SURVEY AND RECORD OF LONDON IN 1919.

The remarkable manner in which familiar aspects, streets, and buildings in London have changed in recent years must be apparent to every Londoner who has been away from the city for even the duration of the war.

During the period of the war in particular, temporary buildings have sprung up on all sides to alter still further the appearance of well-known spots. It is satisfactory to know, therefore, that the Camera Club has undertaken the organisation and direction of a photographic survey of London in the "Peace Year" 1919.

The object of the scheme is to provide a complete photographic record of the appearance of London in the present year, such a record to comprise not only photographs of buildings and monuments of historical interest, but also as many as possible of the ordinary sites and streets of which so little memory remains after frequent rebuildings. It is only necessary for a man of middle age to attempt to recall the London of his youth for the value of this scheme to become apparent.

Holmes dynamo.

Pelapone pumping set.

as soon as it was a bit straight, another move would be ordered. However, as the production of these photographs in an efficient and quick manner very often meant the saving of thousands of valuable British lives and the destruction of those of the enemy, everybody worked with a will for a definite purpose.

The engineering staff consisted of another R.E. and myself, and the total works staff only amounted to 25, including officer, N.C.O.'s, engineers, dispatch rider, cook, storekeeper, and photographers.

The illustrations show some of the plant as used and described, and I might also add that the switch used for the firing of the mines at Messines Ridge eventually found its way on to our switchboard.

Such is a short account of one of the many cases where engineering and electricity, in particular, have come to the aid of our Armies, and have been used to advantage in helping to beat the Hun and save civilisation from a fate that was too horrible to contemplate.

H. Moss.

LANCASHIRE SOCIETY OF MASTER PHOTOGRAPHERS.—A committee meeting of the above society will be held on Tuesday, March 11, at 4 p.m., at the Manchester Chess Club, 65, Market Street, Manchester.

THE OPTICAL SOCIETY.—At the meeting to be held on Thursday next, March 13, at the Imperial College of Science, South Kensington, S.W.7, a paper on "Some Photographic Apparatus Used in Aerial Photography" will be read by Major Charles W. Gamble, R.A.F. Any of those interested in the methods of aerial photography will be made welcome to the meeting.

According to the main outlines of the idea the London area will be divided into sub-areas, in each of which a local secretary will be appointed, and, if possible, a local sub-committee to organise the work; and an appeal is being made in the first instance to London and suburban photographic societies to assist. At the same time, individual workers in every quarter will be welcomed, and arrangements will be made for them to get into touch with local centres, as it is hoped that many of the workers in each area will be local residents. If such a record can be adequately completed (and there is no reason why it should not be, if sufficient help is forthcoming), it should be of enormous value and interest to posterity.

No such complete photographic record has yet been attempted on the lines suggested by the Camera Club. Photographic surveys of London have certainly occupied the attention of many bodies in the past, but in most instances they have been confined to specific series of buildings, etc., of either historical or archaeological interest, or, as in the case of the London Survey, have only dealt with buildings preceding a certain date.

The Camera Club Photographic Survey of London will, however, aim at a much more complete record of the appearance of the Capital in 1919. It is desired to secure photographs of practically every street and building in London and Greater London as it exists at the present day, and even more attention will be given to the ephemeral buildings associated with the war, and which will probably not be in existence next year, than to greater monuments of historical antiquity which will appear much the same in a hundred years' time as they did a century ago. At the same time, these will not be overlooked. The presence of figures in the costume of the moment will not be regarded as detrimental to the record where they occur. The pictorial quality of the prints will, however, be of secondary importance to their value as technically good results.

To carry out the scheme successfully and completely the Camera Club will shortly be making an appeal in the public press to raise a small fund of, say, £100 to meet postage and initial office expenses, as the conduct of the details will involve this amount at least in addition to a considerable amount of time and labour. But the ultimate success of the scheme depends upon the support of the great body of amateur photographers of all ages and classes who are in London and Greater London to-day. It is suggested that all prints shall be of a standard size, and half-plate has been mentioned as the most suitable. These should be made on bromide paper, as it is considered that a well-made, thoroughly fixed and washed bromide print is probably as permanent as a print in any other process.

Standard large-scale sectional maps of London will be provided for each secretary of the photographic societies or other organiser of local groups of workers. The exact situation of the subject recorded and the position from which the picture was taken are to be marked on these maps, with suitable references to the print itself.

Until the survey is complete the Camera Club is undertaking to mount, file, and store the prints, which will be treated in a uniform manner and systematised for reference. The collection will eventually be stored in one of the public museums.

A leaflet describing in detail the whole undertaking is in the press, and will be forwarded to anyone interested who sends a stamped addressed envelope to the Hon. Secretary, Photographic Survey of London, Camera Club, 17, John Street, Adelphi, London, W.C.

DEATH OF MR H ESSEHIGH CORKE

We regret to announce the death, on Monday of last week, February 24, from influenza followed by pneumonia, of Mr H Essenhigh Corke, of Sevenoaks, one of the best-known professional photographers of the younger generation. For many years Mr Corke, in succession to his father, had carried on the business of a photographer in the main street of the pleasant Kentish town. But his work in several directions obtained for him much more than a local reputation. He was a prominent exhibitor at the exhibitions of the Royal Photographic Society and the London Salon, where his essays in pictorial figure work were notable for their artistic and technical quality, and afforded promise of still finer work of this kind. He was also an enthusiastic and very successful photographer of flowers, not merely in monochrome but in the Autochrome process. His work in this field represents some of the finest Autochrome colour transparencies which have been made, and was in great demand for the illustration of books on horticulture. Taking an amateur's interest in his business, Mr Corke was a frequent contributor to the photographic press both in this country and in America, and his papers published in this way during the past ten or fifteen years contain the descriptions of many working methods originating from his own practice. Perhaps none of these has been more widely adopted than that for the making in the studio of portraits giving the effect of having been taken by firelight. Mr Corke worked out this idea very thoroughly, and the first description of his method appeared some years ago in our pages. The photographic profession is the poorer for the loss at the early age of thirty-five of one who took a very real interest in its technical and artistic development. It may be added that the business will be carried on by the deceased's sister, with the assistance of a former very capable assistant, who has just returned from a prisoners' camp in Germany.

REPAIRS TO SHEW CAMERAS—Mr H. T. Ball, who for seventeen years was with Messrs. J. F. Shew and Co., informs us that the firm of Staley, Shew, and Co., having given up business, he is prepared to undertake repairs of any description to reflex, Xit, and others of the Shew cameras. Mr Ball, whose competency in the making and repair of apparatus we know from our own experience, has his workshops at 51, Berwick Street, London, W.1.

Assistants' Notes.

Sight and the Photographer.

It goes without saying that sight is the most important bodily function from a photographic point of view. One might imagine an armless, legless, deaf or dumb person performing some job or other connected with the business, and even one with deficiency of intellect might possess some little photographic skill, but a blind photographer is impossible.

It follows that a photographer's eyes, good or bad, should not be neglected, but accorded at least a modicum of intelligent consideration. A good many procs. hold the belief that the practice of their craft is in itself sufficient ultimately to damage the sight, and judging by the number of workers one meets whose eyes are not so good as they might be, the belief seems reasonable. On the other hand, there are craftsmen of ripe age whose sight is still perfect in spite of years of hard work. The fact is that photography can—not must damage or even destroy the sight of anyone engaged at it, the damage usually being brought about by circumstances many of which are in themselves inconspicuous and therefore unsuspected.

These circumstances depend on the nature of the work, each branch of the business having its own peculiar sources of possible eye strain. In the studio the eye may suffer from constant straining at a too thick or coarse focussing screen, or focussing with the lens stopped down. This is a small thing, but in a very busy shop where the operator may be behind the camera for hours at a stretch, the strain will tell. Where much focussing has to be done, as much light as possible should be allowed through lens and screen, and the work done smartly. Indecision causes strain, and does not improve the final definition of the picture.

The continual switching from short to long focus, occasioned by looking first at the sitter and then at the screen, may tire an eye that is weak, but if the eyes (and the general health also) are strong, this should prove more of an exercise than a strain.

Working with artificial light, an operator may damage his sight by allowing the light to fall directly on his face too often; in other words, by looking long or often at the lamp. Continual switching on and off from full light to semi-darkness, as also going in and out between studio and plate-hanging room, will leave its mark on the sight if carried on to a great extent. The moral here is to keep a fair amount of light in the studio all the time, and have an assistant changing. The latter can keep his or her gaze away from the bright end of the studio without any trouble.

In the dark room the red or yellow lamp is often blamed for tired or failing eyes. This is not strictly right, though the position and strength of the coloured light is very often to blame. A lamp should never be in a position to send direct light into the eye when working, and for this reason a hanging lamp, shedding all its light downwards, is to be recommended. The strength of the light should be as great as the sensitive materials will permit. With regard to the printing room, I would say to those who can please themselves: Discard bromide for galalith, have as much light as you would in your drawing room, and be comfortable.

Where yellow or red light is compulsory all walls should be painted very light: it will obviate much eyestrain in groping about for things which are invisible.

With printing and retouching direct light is mostly used, but in neither case does it so far as my experience and observation go hurt the eye to the same extent as in the case of the dark-room lamp. The difference is this: in one case the eye is working with the image supplied by the direct light and nothing else, in the other the direct rays are worrying the eye and distracting it from its work. This can continue for a long time without the victim being aware of it, even though the eyes and the work may be suffering.

For retouching, the use of direct light, however, is not compulsory; many workers prefer to work against a white or tinted reflector, and one retoucher I know claims that this practice is responsible for his sight being as good as it was twenty years ago. Retouching with weak light, particularly if the negative is yellow or dense causes eye strain, while the remarks on dark room lamps

apply also to extraneous light near a retouching desk. Working on very small heads is apt to be trying, and for this a magnifier may lessen the strain, but it should not be used habitually, otherwise it may become an indispensable crutch.

Spotting and working-up require sight that is perfectly free from astigmatism, and when done by anyone whose sight is not normal, and not corrected by glasses, this work will greatly aggravate the weakness. At the slightest sign of strain the lighting conditions should be examined, and if not at fault astigmatism should be suspected and the eyes tested. Spectacles, however, are not likely to cure bad sight; they will correct the vision and so do away with strain, but that is all.

Before going any further it may be as well to say that this article does not pretend to deal with its subject from any but a purely photographic standpoint. The many defects of vision caused by such things as nerves, bad blood, cigarettes, etc., are not within my scope, and when a photographer's eyes give trouble it rests with him or his doctor to decide whether his craft is to blame or not; it is always possible that some outside influence is causing the mischief. At the same time, a few remarks on the care of the sight may not be out of place. Tired or overworked eyes can be benefited by bathing, and any chemist will make up an eye-bath cheaply. The simplest and safest of these is boric acid.

Sight can be greatly improved by country walking, particularly in districts where long clear views prevail. In my own experience I find nothing to equal daily gazing at landscape the foreground of which is mostly green, with distant planes stretching to far off mountains. Unfortunately, we cannot always enjoy this kind of cure for tired eyes, but in any case and at all times it pays a photographer to care for his eyes, even if it means a little extra trouble. This applies particularly to young workers. In the vigour of youth details are not so readily noticed as they are in after years, and a young enthusiast may go on working in conditions which are bad for the sight without worrying until the mischief is done. Years after it may cost a good deal to undo what a little forethought could have prevented.—THERMIT.

Patent News.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

MEASURING FOCAL LENGTH.—No. 120,984 (November 30, 1917).

The invention relates to an apparatus for measuring the focal length of lenses, whether spherical, cylindrical or prismatic or of any combination of such forms, and for indicating the optical centre, the axis of the cylinder of a cylindrical lens or the position of the base of the prism of a prismatic lens.

The invention consists in an apparatus comprising certain essential parts defined by the appended claims.

Fig. 1 of the accompanying drawings is a vertical section of an apparatus according to the invention. Fig. 2 is a view showing the hair lines hereinafter referred to.

The apparatus shown comprises a telescope, 1, provided with an eye-piece attachment fitted with an eye-lens, 3, and a field lens, 3', beyond which latter are cross-hair lines, 2, one of which is graduated, the eye-piece attachment being telescopically adjustable to bring the hair lines into the focus of the optical system constituted by the lenses, 3 and 3'.

The hair lines are carried by a tube, 2', rotatable around an axis coincident with the axis of the telescope, 1, and carrying a head, 2^a, provided with a graduated scale.

Disposed in the optical axis of the telescope, 1, is an auxiliary lens, 4, in the principal focus of which is clamped the lens, 5, to be measured or tested.

The clamp employed comprises four spring-pressed gripping pins (of which two are shown at 5') in which the lens may be securely held in central position, there being no adjustment or movement of the clamp during the test

Mounted so as to be slidable towards and away from the lens, 4, is a tubular fitting, 6, in which are received a small electric lamp, 7, or other means of illumination, a diaphragm, 8, or the like having a central pinhole aperture disposed between the lens, 4, and the lamp, 7, and a very short focus lens or globule, 9, between the diaphragm, 8, and the lens, 4, the short focus lens or globule, 9, being adapted to produce a greatly reduced image of the aperture of the diaphragm, 8.

The tubular fitting, 6, is movable along the optical axis of the telescope by means of a rack, 10, and pinion, 11, or other mechanism. For indicating the extent of movement, there is fitted to rotate with the pinion, 11, a disc, 12, provided with graduations, the scale divisions being preferably in diopters.

Assume that the lens to be measured is a simple spherical lens. The lens, 5, having been clamped in position, the tubular fitting, 6, is moved axially until a sharply defined image of the aperture is seen by the observer looking into the eye-lens, 3. If the

Fig. 1.

lens, 5, be correctly centred, this image is at the point of intersection of the hair lines. The focus or foci of the lens, 5, is simply read on the diopter scale on the disc, 12.

If the lens, 5, be decentered or prismatic, the image of the aperture will be offset from the said point of intersection of the hair lines. The tube, 2', is then rotated until the image is bisected by the graduated hair line. The distance of the point of intersection of the two hair lines from the point of bisection of the image is a measure of the amount of decentering or of prismatic power. The reading on the scale on the head, 2^a, which denotes the extent of rotational movement of the hair lines is a measure of the position of the base of the prism.

If the lens, 5, to be measured by cylindrical, the image of the aperture is a line of light. To ascertain the position of the axis of the cylinder, the tube, 2', is rotated until the graduated hair line is seen in coincidence with or parallel to the line of light; the extent of rotational movement of the tube, 2', as indicated on the scale on the head, 2^a, being a measure of the angular relation of the cylinder axis to the lens. John Trotter, 40, Gordon Street, Glasgow.

Mr. WM. HAIG PARRY, of Middlesbrough, having been recently demobilised from the Royal Air Force, has dissolved partnership with his sisters, and is now commencing business on his own account at 14, Cargo Fleet Road, Middlesbrough, as an engineering, shipping, and commercial photographer.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, March 4, Mr. J. F. Warburg in the chair.

A paper on "Hints and Suggestions for Use in the Dark Room and Workroom," by Mr. Vivian Jobling, disclosed the author to be the possessor of an immense amount of ingenuity and imagination in the design and construction of various little contrivances for dark-room work. It would be impossible to mention all the hints which Mr. Jobling gave, but a few may be singled out. For rendering the work bench impervious to liquids, he treated it with paraffin wax, forcing the wax into the pores of the wood by means of a hot laundry iron. In order to obviate the formation of air bells on negatives, as a result of mixing the developer with sprated water from the tap, he kept a few bottles of boiled water on the dark-room shelf, fitting these with two glass tubes (one of small diameter) passed through a cork; the water could be readily poured from the larger tube, air entering through the smaller. When leaving bottles after use, Mr. Jobling placed cardboard caps over them so as to prevent dust from settling on the rims. A method of making up 50 per cent. hypo solution without weighing consisted in taking a 40-oz. bottle and, after filling it with water and then pouring out 10½ oz., making a mark at the level of the water. If then hypo be added until the solution fills the bottle, a 50 per cent. solution will result, 20 ozs. of hypo increasing the bulk of the water in which it is dissolved by 1½ ozs.

Mr. Jobling described some very neat plate separators made for the development of a number of small plates in a large dish. One pattern of these consisted of a thin metal cross, each arm of the cross being cut half way through, and then turned up at right angles with the original plane of the metal. Other separators consisted of thin wax paper, perforated in places with a half round chisel, and the perforated semi-circular portion turned up at right angles. It was found that by making these upstanding half moons all in the same direction that an even flow of developer was obtained, and there were no wave markings on the plates, as was the case when the flow of developer was obstructed by a part of the separator. Another little device of Mr. Jobling's consisted in L-shaped pieces of thin black paper for the marking of lantern slides. Mr. Jobling preferred these latter to the single marking pieces, since the squareness of two adjacent sides was determined beforehand when cutting the pieces by the aid of a template. A final hint related to the cutting down of glass for use as lantern slide cover glasses, and Mr. Jobling showed a very ingenious device for cutting plates of vest-pocket size from five by fours.

After some brief discussion, in which the Rev. F. C. Lambert, Mr. G. C. Weston, Lieut. Jennings and others took part, the hearty thanks of the meeting were accorded to the lecturer.

CROYDON CAMERA CLUB

SOMEBODY has somewhere said that when any particular art becomes largely talked about it is decadent and dying. If this be true, then photographic pictorialism must be in a bad way. In another aspect, much modern work can be considered to be habitually dying if it is deemed to be synonymous with the art of the camera. At Croydon during the last six months the so-called ethics of picture-making have been dealt with many times by various teachers and lecturers. In the main this science of artistic duty, as expounded, has been based on the broad principle of burying a more or less-despised photographic image with powder or paint, and holding a sort of wild Irish wake while it slowly gives up the ghost.

If the operator does not happen to be a trained artist, delirium usually follows the departure of sanity, but, after all, delirium is a creation, the other emphatically is not—"art" *versus* piffing "selection," so to speak. It is this buoyant feature which enables the artist, elevated purely by the process, to float serenely about those who stick to earth, and what they consider to be inherent limitations of the craft. If only the former style of art had anything tangible to grasp, a neck, for instance, assuredly by this time its face would be blacker than blacklead, if certain sorely tried members had had the pleasure of meeting it on the level.

Last week, Mr. T. H. B. Scott pluckily turned up, looking and feeling none the better for a recent bout of the "flu," to chat about a collection of his own landscapes, and very good indeed and pleasant to gaze upon they were. Half-tone illustrations from pictures by other workers were also included, all nicely mounted on white blotting-paper.

The combined collection represented a part of the output of the East Anglian Photographic Federation, which, he said, was striving to follow the famous Norwich school of landscape painters by incorporating with landscapes a feeling of air and space, a definite aim tending to produce better things than desultory and haphazard work. The influence of this school, and the work of "Old Thorne" and Constable on British and French landscape art, was then briefly sketched. As regards criticism, that of the destructive kind, anxious and eager to find fault, was as easy in its inception as it was injurious in its application. One should endeavour to criticise sympathetically, and, so far as possible, appreciatively.

The rest of Mr. Scott's remarks consisted chiefly of well balanced criticism of the exhibits on the walls. In one respect they fell far short of what one had a right to expect. Almost invariably the photographic artist towers above the painter or draughtsman when it comes to a generous recognition of his own genius. Too frequently the painter diminishes the appeal of a picture by openly stating he regards it as but a stepping stone to bigger things; and Mr. Scott seemed inclined to follow this example. Having now been warned, it is hoped he will be more careful. By all means let him talk confidently about the future, but only in terms of relative greatness. The traditions of the art must be maintained.

A most hearty vote of thanks, and a drop of something (the last of the Mohicans) to keep the cold out on the journey home, were accorded the lecturer, who was much appreciated by an infuriated audience, one graded to this state by an enforced consumption of ginger ale or Croydon water. And such ginger ale. The pretty things that were said about the powers that be would lose all virtue if paraphrased. Failing instant departmental action it is understood that Mr. Harper in full art-paint will be dispatched to Westminster, with reflex camera and fitted gramophone horn sky shade in skrimishing formation. These, with filters, telephoto lenses, changing bags, tripod, and other essentials distributed about his person, impart an aspect sufficiently terrifying to bring any Government to its knees.

Commercial & Legal Intelligence.

SHOPS ACT. At the City Police Court, York, last week, Thomas J. Hanstock, of 11, Clarence Street, photographer, was summoned for having kept his shop open during prohibited hours on February 19. The Chief Constable stated that the defendant had contravened the Shops Act by keeping open on Wednesday afternoon when he should have closed. Sergeant J. Croft spoke to visiting the defendant's shop on Wednesday, February 19. It was open. He asked the defendant if he closed the shop for a half day during the week.

and the reply was that he did not close. The shop was kept open for the convenience of the customers on Wednesday afternoons. The Chief Constable said that photography was not a trade exempted from the Order. Defendant handed to the magistrates a copy of a regulation made by the York City Council under the Order by which "fancy postcard and photograph dealers and toy dealers" were exempted from its provisions. The Chief Constable maintained that defendant was not a "photograph dealer," but a photographer. Mr. Miles: Your contention is that the regulation only applies to persons who sell postcards or photographs, and not to people who take orders for photographs? The Chief Constable: Yes. Photographers have never made any application to be exempt. Defendant said he was a photograph dealer and manufacturer, as well as a photographer. He only kept open on Wednesdays because hundreds of people had been diligently working overtime during the war and had only Wednesday afternoons off. It had not been his intention to do so much work, but he felt that he ought to oblige poor people who wanted to send photographs to their husbands at the front. He had frequently worked without stopping for dinner, not for greed of money, but because he wanted to console these people. He admitted that other photographers in the city closed on Wednesday afternoons. The chairman said a fine of 7s. 6d. would be imposed. Unless the order was obeyed by the defendant he would have a monopoly of taking photographs on Wednesday afternoons, which was not fair to the others. There was, perhaps, some excuse from the defendant's point of view. Defendant said he did not intend to keep open on Wednesday afternoons, but he asked the Bench to bear in mind that under the order there was nothing to prevent him or any other photographer from taking photographs by appointment on Wednesday afternoons.

FRAUD IN OIL PORTRAITS.—A canvasser of portraits in oils, named Armin Gross, was last week sentenced to six months' hard labour at the Maidstone Assizes. The circumstances of the case had previously been heard before the Bromley magistrates, when (Gross (41), described as a portrait specialist, of 6, Plympton Road, London, N.W., was charged with obtaining £50 by alleged false pretences from Mrs. E. J. Armstrong, at Chislehurst, between February 1, 1918, and April 25, 1918; and Gertrude Green, of 33, St. James Square, Holland Park, London, was summoned for aiding and abetting in the commission of the alleged offence. About the end of January, 1918, Mrs. Armstrong, a widow, who was staying at Cranmore Place, Chislehurst, was visited first by the female defendant, who spoke about helping British artists, and said they were in a bad way owing to the war. She said she was travelling in that district to get orders to help support them. She showed Mrs. Armstrong some miniature samples, and Mrs. Armstrong decided to have a miniature painting of her late son, a lieutenant in the Sherwood Foresters, who was killed. The price agreed upon was 10 guineas, and Mrs. Armstrong understood that it was done to help artists distressed through the war. Later the male defendant appeared at Chislehurst. He brought a small crayon drawing for the miniature and carried on the idea of charitable help for distressed artists. He produced for her inspection a partly finished portrait of the late Sir Stanley Maude, and said it was an order he had received from the family. He asked Mrs. Armstrong if she would like a picture of her son done by the same artist, and said the price of a painting similar to the one produced would be £50. He represented that it was "frightfully" cheap, and that the usual price charged by this artist, who was impoverished by the war, was 150 guineas. He, however, said he would get it done for 50 guineas, and having been told that it would be done by a poor artist, Mrs. Armstrong was influenced to give an order for a portrait to be done. She believed it would be a charitable action, and that she was getting the painting very cheap. About a week later the male defendant called with the finished miniature ordered through Mrs. Green. Mrs. Armstrong said she didn't like it, and had another one. On February 12, Mrs. Armstrong gave him a cheque for £63, for which he gave her a receipt, with an intimation that 10 per cent. of the money would be given to any charitable institution she cared to select, and she chose the Lord Roberts' Workshops' Fund. On April 23 Gross called with a man named Butler, who said he was the artist. The painting was produced. Mrs. Armstrong said she did not like it. Gross said he was sorry, and the picture was taken away and

altered. On April 25 Mrs. Armstrong received a letter from Gross in the following terms:—

"I am pleased to say that the oil painting is now quite ready. The alteration on the cheek and mouth has turned out most successfully. The artist has been working on it ever since he brought it back. I ordered a case to pack it in, which will be ready in ten days' time. The cost in all for packing, carriage, and insurance will be £1 5s. I have gone to considerable expense in pleasing you, and as I have every confidence in the artist who painted the picture, and with whom I have an agreement by the year, I was more sure of him pleasing you than anyone else. I pay him £5 a week and give him three commissions per year, which works out at £87 per painting. I sincerely hope you will see that I am nothing in pocket, at least that I shall not be the loser. I feel you did not mind whatever the cost if it pleased you. . . . I am enclosing an account of actual money I laid out, and leave it entirely to you to do what you think is right."

The account enclosed with the letter was as follows:—

One oil painting	£87 0 0
One miniature	8 8 0
One miniature	8 8 0
One black and white portrait	6 6 0
One miniature case	4 10 6
One small gilt frame for second miniature...	1 1 0
One frame black and white	0 12 6
One frame for oil painting	4 10 0
Packing case, insurance, etc.	1 5 0

£122 1 0

Mrs. Armstrong then wrote to Gross, referring him to her solicitors, and subsequently Gross wrote in reply as follows:—

"The painting will be despatched to-day. I was more than surprised at your letter. I certainly will not take any action, as what I did was entirely on my own risk in doing my best for you. Surely you quite understand that it is an extra expense doing a larger painting, also a large frame. However, if you think I am not entitled to any more we will leave it at that, only I will never in future do for anyone more than first arranged. In any case I shall be glad to know if you are entirely pleased."

Frank Richard Webb, manager to John B. Smith, of 117, Hampstead Road, London, said he supplied portrait frames similar to the one produced to the prisoner Gross. The present-day price was about 20s.; the pre-war price was 11s. 3d.

Ottlywell Butler, of 45, Canonbury Square, London, an artist, said he painted the portrait produced on an order from Gross. Witness was paid about £3 for it. Witness painted it from the photograph produced. He had never received £150 for a picture from anyone, and the utmost he had received from the prisoner Gross for a picture was about £10. On a few occasions witness had received as much as 40 guineas for a picture from life, after a series of sittings. For a picture of the size of the painting produced witness was usually paid £2 or £2 10s.

Mr. Justice Horridge did not think the charge of obtaining money by false pretences could be sustained as the indictment was not properly framed, and the jury found prisoner guilty on the second count of endeavouring to obtain money by false pretences.

It was stated that there had been a good many complaints about prisoner, who was sentenced to six months' hard labour.

News and Notes.

MESSRS. RAJAR, LIMITED, are issuing a new printing paper, "Rajo," for which they claim "gaslight quality" as regards the blacks and "bromide quality" as regards the gradation.

LANCASHIRE SOCIETY OF MASTER PHOTOGRAPHERS.—The first dinner arranged by the society was held at the "Albion" Hotel, Piccadilly, Manchester, on Tuesday, February 25, and was in every respect a huge success. The number that sat down was fifty-seven, the accommodation being fully taxed. A most enjoyable evening was spent. The president, Mr. N. S. Kay, presided, and the important duties of M.C. were in the most capable hands of Mr. F. Kenworthy. The musical programme was contributed to by Madame Alice Sampson, Miss M. Philippott, Mr. Ryder Boys, Mr. F. Kenworthy, Mr. N. S. Kay, Councillor Sarnie, Mr. F. Mills, Mr. F. Turner, and Mr. W. Dunkerley, who accompanied in a most able and efficient manner.

Mr. Marsden Jackson, tenor, of Manchester, was unavoidably prevented from contributing to the musical programme owing to the prevailing epidemic. An excellent menu had been prepared, and full justice was done to the same. The toast of the P.P.A. was responded to by Mr. Chidley, of Chester, in a very able manner, and his speech was very well received by those present. The society is holding an exhibition of members' work in Blackpool on Tuesday, May 27, and following days, and it is hoped that every member will make a note of the date, as the annual general meeting and election of officers will also take place on May 27. Fuller particulars will be announced in due course. Applications for membership should be addressed to the Hon. Sec., Mr. F. Read, 14, Balfour Road, Southport.

BRITISH SCIENTIFIC PRODUCTS EXHIBITION, 1919.—The King has graciously consented to act as president of the British Scientific Products Exhibition, 1919, which will be held at the Central Hall, Westminster, during the month of July. The president of the Exhibition is the Marquess of Crewe, K.G., and Professor R. A. Gregory is chairman of the organising committee.

The British Science Guild has been encouraged to organise this exhibition by the success which attended that held at King's College last summer, and the more recent exhibition at Manchester. Now that many inventions can be shown which could not be put before the public during the war, there is every prospect that this year's exhibition will be even more successful than its predecessors. The objects of the exhibition will be to illustrate recent progress in British science and invention and to help the establishment and development of new British industries. Such an exhibition will enable new appliances and devices to be displayed before a large public and will provide progressive manufacturers with an opportunity of examining inventions likely to be of service to them, thus serving as a kind of clearing-house for inventors and manufacturers, as well as illustrating developments in science and industry.

The exhibition will include sections dealing with chemistry, metallurgy, physics, agriculture and foods, mechanical and electrical engineering, education, paper, illustration and typography, medicine and surgery, fuels, aircraft, and textiles. Firms desirous of exhibiting are invited to communicate with the Organising Secretary, Mr. F. S. Spiers, 82, Victoria Street, London, S.W.1.

Correspondence.

THE ASSISTANT QUESTION.

To the Editors.

Gentlemen,—As a recently discharged service man who has just resumed taking in your valuable journal, I have been struck by the fact that though nearly all other trades and professions have their trade unions, there still seems to be no one bold enough to improve the status of photographic assistants. Glancing down the Situations Vacant and Wanted we still find the "folly qualified," "operator-retoucher," "capable manager," etc., pleading for £3 or £4 per week; whilst generous firms offer a similar princely salary for expert assistants. Surely a highly skilled technical calling like photography should be paid on a higher scale than this?

In view of this low standard of wages for highly skilled work, it seems to me quite impossible and unreasonable to expect a scheme of education in photography to be seriously considered if the reward for diligence is £4 per week. Are we to admit that prices for work are so cut that employers are unable to raise this standard of pay? If so, cannot prices for work be controlled by the P.P.A.? By all means encourage education for assistants, but elevate the dignity of the profession by creating positions worthy of being filled and studying for. A standard wage is undoubtedly needed, and the profession should be taken in hand and modelled on the organisation of the chemists and druggists, as suggested in your paper. Let the P.P.A. make a determined effort to make photography premier among the higher professions instead of the reverse.—Yours,
E. F.

DEVELOPER POISONING.

To the Editors.

Gentlemen,—In reference to Mr. A. England's letter in the "B. J." on developer poisoning and the use of a pair of forceps for developing bromide prints, I think this is a good thing to use without putting the hands into the developer; but, of course, this would not answer in the case of developing postcards, where a quantity are developed together. I have been a great sufferer from metal poisoning on the hands and arms, and for the last two years I have worn thick rubber gloves, not the photographic kind, but those gloves which I obtained from an ironmonger's shop and which I believe are used by motor mechanics to protect the hands. Anyhow, the gloves are a good thickness, and they do not puncture like the thin ones. The cost of the gloves is 10s. 6d. I can work just as well with them as without, and I should advise any photographer suffering from poisoning to use them. Of course, they are a little trouble at first, but you soon get used to them. Also I should advise the use of Ujah ointment, which I have found a good thing for metal poisoning.—Yours faithfully,

G. HARPER.

The Studio, 15, Market Place, Abingdon.

"CINEMATOGRAPH" OR "KINEMATOGRAPH"?

To the Editors.

Gentlemen,—In your issue of February 21 "Kino" states that the name "kinema" was first used for an English patent in the 'sixties or 'seventies. I have failed to find any trace of this, neither does Henry V. Hopwood in "Living Pictures," the most complete and painstaking historical survey of cinematography in existence, betray any knowledge of the alleged fact.

However, even "kinema"—a purely Greek word—is not "kinematograph," and I challenge "Kino" to produce a single example of the British employment of the latter, spelt with a "k," before 1891-5, during which period the word "cinematograph" was introduced by M. Bouly and M. Lumière.

The particular spelling adopted by the Patent Office is entirely irrelevant. This admirable Government Department is not, and does not profess to be, an authority on orthography, like the French Academy, but merely records and indexes what is placed before it. I have, by the way, looked over a list of a few authoritative text-books of recent years, and find that, out of a dozen taken at random, ten spell cinematograph with a "c." The press and journalism generally is also overwhelmingly in favour of that course.

"Kino" seems quite to have missed the real point at issue. This is, that it is customary, with few exceptions, in English, French, and Latin words derived from Greek ones beginning with or containing "k" to convert it into a "c," whereas the German usage is to retain the "k." The question faces us, Why should we deviate from our general practice and prefer the German way to the French in the case of a word first used in France?

But out of his own mouth "Kino" is unconsciously convicted, for he spells bioscope with a "c." Now, bioscope comes from the Greek, *bios*, life, and *skopeo*, I look. Hence "Kino" ought to have written "bioskop." Why this ridiculous and un-English inconsistency?

The Germans *do* write bioskop, teleskop, mikroskop, stereoskop, etc. They also write kinematograph, kamera, kamerad, kampf, (camp), kappe (cap), karikatur, kasein, katechu, katopter, katze (cat), klamme, kollimator, kolloidum, kopie (print), kork, kristall, artikel, objektar, and so on. Thus it is evident that, not only in words derived from the Greek but in many others, the Germans instinctively use the "k" where an Englishman or Frenchman would employ "c." Surely, in view of so many instances, let alone the undoubted French origin of the word, all British precedent leans to "cinematograph" rather than "kinematograph."

It is only a minority who now favour the latter, though that minority admittedly includes some who have done yeoman service in motion picture work. Let them bow to the spirit of the times, and prove their patriotism by dropping that Teutonic "k."—Yours faithfully,

A. LOCKETT.

11, Cheriton Square, Balham, S.W.17, March 1, 1919.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

T. S.—The Almanac was published on February 6, and as the whole of the edition has been delivered to the trade our publishers are no longer able to supply copies.

SILAS WEIR.—We deal with your question in another column under "Ex Cathedra."

M. E. F.—No better book, as we have said a good many times, than "The Science and Practice of Photography," by Chapman Jones.

J. RITCHIE.—We have never seen advertisements for waste trimmings from prints apart from those of the firms regularly offering to purchase silver residues.

T. R.—There might be profit in it, but it would take a very considerable time to get a connection together. We should regard the proposal with a good deal of distrust.

E. F.—The best means to take is to soak the silk in a solution of sodium bisulphite or, if this is not obtainable, ordinary soda sulphite with some oxalic acid added to it.

F. L. C.—It is rather unusual to experience the difficulty in buying from a wholesale house, but surely from your local chemist to whom you are known you could obtain sufficient for your purposes.

G. N.—It would not work as you suggest. If you add acid to a solution of hypo sulphur is thrown down in a very short time. Sulphite prevents the action, and that is why it is used in making acid fixing baths.

S. F. SLAUGHTER.—Albumenised paper has not been an article of commerce for a good many years. The only way in which you could perhaps get a few sheets is by spending a shilling or so on an advertisement.

S. H.—You cannot assume that very much value attaches to the fact of the provisional specification having been granted. Search for possible anticipation of the invention is not made until the specification is filed.

J. S.—In some districts the police require a canvasser for photographic portraits to take out a drawker's licence, but the practice varies a good deal in different parts of the country. You should apply for information to some head police office.

R. A. F.—There is no question which you should choose—viz., electric. In comparison, any gas installation is very greatly inferior in power, and has the drawback of producing heat to an extent which makes it impossible in a studio of small size.

C. R.—Precisely what you suggest was given a commercial trial some years ago, but it was a failure. It is a messy business. The solution stains anything it touches, and it is difficult to know when development is complete, and in any case you have to have some makeshift dark-room in order to put the plates into the solution. No wonder then that altogether the game was not found worth the candle.

B. H.—1. See article on "The Surroundings of the Studio" which appeared in the "B.J." of February 28. 2. Fluted glass is of no use to stop sunlight. Use zinc white stippled on, or starch whitening. 3. For the Boardman reflector use "Blanco," a kind of pipeclay. 4. We think you will find the Cooper Hewitt light quite satisfactory. It is about equal to good daylight.

G. R. S.—You have no legal right to claim the opportunity for making specimen portraits on your own account, although most decent master photographers are ready to give their assistants the facility for so doing. We know that there have been instances where this has been a sore point between master and assistant, and we should be glad to see a more general practice in the direction of encouraging assistant operators to obtain examples of their work.

C. F.—1. If you mean sensitised cards with deckle edge, so far as we know they have not been put on the market here by any of the British firms. 2. We do not know a combined trimmer and beveller of Merrett's, but a line to Messrs. Merrett, Bros., Trowbridge, Wilts., would bring you particulars. 3. The best plan is to tone to a sepia by the ordinary bleach and sulphide process, and then to carry out further toning in the ordinary gold and sulphocyanide bath.

COPYRIGHT.—An appointment was made with a photographer and a photograph taken of the members of a well-known local committee about a fortnight ago and an order received and executed for postcards and enlargements. Last week a reproduction of this group appeared in a well-known paper. Neither the photographer nor any member of the committee have any idea how the paper obtained a copy to reproduce. (1) Is the paper, or the individual who sent the copy, or are both actionable for reproduction without authority? (2) Can the editor of the paper be made to divulge name of sender of photograph?—T. E.

(1) We should say that if the paper has reproduced the photograph without having received a licence from the person who owns the copyright, it is certainly liable for infringement, but it is doubtful whether the action could be maintained against the person who offered the photograph for reproduction. We imagine it would be difficult to show in respect to the latter that he or she caused the photograph to be reproduced. (2) By no means that we are aware of.

The British Journal of Photography.

Line Advertisements.

Charges for Insertion.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind the scale of charges. They will thus save themselves delay in the publication of their announcements. A Schedule by which an advertisement can be correctly priced will be sent on request.

Net Prepaid Line Advertisements.

12 words or less	1/-
Extra words	1d. per word.

(No reduction for a series.)

Special Note. Advt's under a Box Number.

"Box No." and office address charged as 6 words.
For forwarding replies add ... 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.

Orders to repeat an adv't must be accompanied by the advertisement as previously printed.

Advertisements are not accepted over the telephone or by telegram.

The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.

Displayed Adv'ts should reach the Publishers Monday morning.

The insertion of an Advertisement in any definite issue cannot be guaranteed.

SUMMARY.

We regret to announce the death on Tuesday in last week of Mr. C. Welborne Piper, a member of the staff of the "British Journal," and widely known for his writings and experimental work in photographic chemistry and optics. (P. 129.)

In a contributed article, Mr. Ernest Manley gives working details for the production of purple bromide prints by bleaching and re-development in daylight. (P. 123.)

The article this week by "Practicus" deals generally with the arrangements for the postcard studio, such as the utilisation of small working space, the making of a number of negatives on one plate, and the production of the prints by enlarging. (P. 125.)

The optical conditions, which in practice may reduce the efficiency of the local-plane shutter to as low a figure as 60 per cent., are the subject of an article on page 123, in which the effect of the distance between the shutter-blind and the sensitive surface, particularly in the use of a large-aperture lens, is shown.

The development transfer paper known as Kerotype, invented by Messrs. Middleton and Kent, may be used for the production of prints upon supports of all kinds. In reprinting an account of the recent demonstration before the Royal Photographic Society, we are enabled to add a list of British patent specifications relating to stripping film. (P. 127.)

At the Royal Photographic Society, on Monday evening last, Mr. W. B. Appleton, of Messrs. Taylor, Taylor, and Holson, gave a lecture on and demonstration of the improvements made by his firm in the manufacture of lenses for aerial photography. Mr. Hawalkus, of Messrs. Ross, Limited, added some notes on the work of his firm. (P. 133.)

Details of a camera for aeroplane photography driven by power and making exposures automatically are given in Patent News. (P. 131.)

Portable studios, rapid fixing baths, half-watt lamps, sensitising silk, the Shops Act, and other matters are the subject of brief replies to correspondents. (P. 135.)

The presence of fog in the studio is a cause of negatives, deficient in brilliancy, which may be mitigated in part by screening the source of light, whether day or artificial, and in part by the use of a lens of shorter focus. (P. 122.)

Yellowing of a lens with age or by insufficient care is a thing not to be disregarded in purchasing an instrument secondhand. (P. 121.)

The camera of vest-pocket size may have its use in the studio in the way of making a portrait unknown to the sitter. (P. 122.)

EX-CATHEDRA.

Complete Development. The maxim which is rightly emphasised to makers of bromide prints, namely, to develop thoroughly, is one which even now, although it has been repeated over and over again, is largely disregarded. Neglect of it is one of the chief causes of unsatisfactory quality in sepia-toned prints, the results of toning an image which has been rapidly and, therefore, superficially developed being greatly inferior to those in which development has been carried more deeply into the film. One rule which has been given for the guidance of bromide printers is that the time of development should be at least three minutes, and exposure adjusted accordingly in order that the print at the end of this period of development should not exhibit the effects of over-exposure. But papers and developers having their particular idiosyncrasies, perhaps a more usefully applied rule for discovering whether prints are receiving this "full" development is to immerse half of a print only in the developer, and after the expiration of, say, half a minute to allow the developer to act upon the whole. If, then, development can be continued so as to yield a satisfactory print which does not show a difference between the two halves, the worker may be satisfied that his development is of the required fulness. On the other hand, a difference between the two halves will indicate that exposure can be advantageously cut down.

Colour of Second-hand Lenses.

Those who are buying secondhand lenses will do well to give the question of colour some consideration. As is well known, long exposure to damp or atmospheric conditions tend to discolour the glass of the lens, or cause the balsam cementing the components to deteriorate with the same result. Some secondhand lenses that we have seen suffer from this very badly, the glass having quite a yellow tinge, in others, though existent, the defect is not so apparent, but if present the marked aperture of the instrument does not represent its actual working speed. We had one such lens that when examined in a casual way showed little or nothing the matter, but when placed against a sheet of pure white writing paper a slight discolouration was at once noticed. Slight though this was, it had a marked slowing action when using ordinary plates, though when orthochromatic emulsions were employed this to a large extent disappeared. Those having such instruments will do well to send them to one of the firms advertising in the advertisement columns of this Journal for repolishing or recementing of the glasses as the case may be, while if buying a secondhand instrument prospective buyers should be on the watch for a defect, which, though it might easily pass unnoticed, reduces the actual value of a lens very considerably. This discolouration is

perhaps more frequently met with in the older instruments than in the modern anastigmats, unless these have been very much exposed to bad conditions, but it is a condition of things that all owners of good cemented anastigmats will do well to guard against.

* * *

Camouflaging the Camera. We commented recently upon the use of the small camera in certain branches of photographic work where its advantages may be turned to good account. A further instance of its value as a supplementary instrument in the studio was told to us the other day by a professional friend. He was commissioned to make a portrait of a child of whom previous experience had taught him that, however pleasing might be the expression on the little sitter's face, it instinctively froze directly the operator made a move towards the camera. The studio instrument was prepared in the usual way, and in front of it was placed a table with piles of books, etc., very carefully arranged to conceal a previously focussed vest-pocket camera, with its shutter set ready for an exposure. The usual attempts were made with the studio instrument and with small hope of obtaining a satisfactory picture. The operator turned away rather disgusted. Almost at once the little sitter was herself again, and casually, as it were, turning to the table the operator pressed down the shutter release of the vest-pocket camera, covering the action as if by taking up a book. As was expected, the exposures made with the studio camera were failures from the point of view of expression, but the small camera yielded a lifelike and pleasing portrait. The negative was carefully enlarged, and the result was an order for some dozens of prints. The idea of camouflaging a small camera should prove of value to those photographers who have to take portraits of nervy sitters, since the exposure may be made at a selected opportunity without the sitter being aware of it. Such a plan should help in overcoming many a difficulty in this respect. Though the negative is small, the quality can be of the best, and the resulting enlargements with a little working-up should give no indication whatever that they are not contact prints from large-sized original negatives.

* * *

Varnishing Negatives. Few photographers at the present time varnish their negatives, nor when ordinary bromide printing or enlarging is to be the medium is this course really necessary. But when a number of P.O.P. carbon or platinum prints are required from one negative, and the printing is done in the semi-open air for the most part, in damp weather it is a wise precaution to give the negatives a coat of ordinary cold varnish. Many present-day operators, however, find a great difficulty in getting an even coat of varnish over the entire plate by the ordinary method, and if this is not done there is a tendency for the varnish to dry in ridges, which means, of course, corresponding markings on the prints. Varnishing negatives by flowing the varnish on and tilting the plate at various angles until the whole is covered, and then draining the surplus back into the bottle, is an operation that requires a certain amount of skill, which can only be obtained with practice. We have for some time past varnished our negatives with an ordinary camel-hair (or hog-hair) brush. The exact kind is not very important, provided that it is well made and free from loose hairs. For this method, though not strictly orthodox, we may claim that it is comparatively easy to put a light but even coat of varnish on the film. None of the varnish need be got upon the back of the

plate, and negatives may be very rapidly treated. Care should be taken not to get the brush too full of the varnish, or uneven coating may result. To those who have had no experience of varnishing negatives this alternative method may be recommended, although the essential feature of it is that a thin coating is rapidly applied.

FOG IN THE STUDIO.

IN many localities, notably in the London district, the state of the atmosphere has left much to be desired from the photographer's point of view. Not only has there been an actual deficiency of light through the presence of more or less yellow fogs, but there has been great difficulty in securing brilliant negatives on days when the light was fairly good, because of the general haziness of the atmosphere. Many photographers suffer from this fogginess without quite being aware of the actual cause of it. A simple experiment which will show in a rough way how much fog is present in any room at various distances can be made with the aid of two ordinary black velvet focusing cloths, velvet being chosen because it has less reflecting power than any other material in ordinary use. One piece of velvet is crumpled up so that some parts produce deep shadow and put on a table in the position usually occupied by the sitter. The operator then stands by the camera at the distance at which a full-length portrait would be taken, and holds up the other about a foot from his eyes so that it half covers the piece on the table. If there is any appreciable amount of haze present he will find that the deep shadows on the distant piece appear quite grey in comparison with those on the piece which he is holding, and at once finds an explanation of the flat negatives which he has been obtaining.

Having established the existence of the fog, our aim is now to minimise its effects, and there are many methods by which this end may be partially attained which, when put together, result in a substantial improvement in the quality of the negatives. In the first place, the studio windows should be kept clean, so that as small an area of glass as will give the desired lighting will be needed to obtain short exposures. By thus closing out all unnecessary light we reduce the general illumination of the fog and get a much brighter image. This can perhaps better be seen when working with artificial light. If we build the lamps in with screens or backgrounds so that the light falls upon the sitter only and none reaches any other part of the studio, there are only three or four feet of fog to work through, while if the whole of the studio is illuminated the amount is greatly increased.

In foggy weather the lighting of the sitter may be more concentrated than is usually necessary, as a more vigorous negative will then be obtained, and printing can be carried on until the shadows are of sufficient depth. Windows become coated with smoke in a day or two in the winter and act as undesirable diffusers, so that it is advisable to clean at least the panes which it is intended to leave unscreened.

A fairly warm temperature and good ventilation tend to reduce fog and to clear it away quickly. We have often noticed that a room or studio has remained foggy long after it has become fairly clear outside. When the necessary power is available, an electric fan will do much to establish a current of air, which should be directed towards an open window or door. A proper exhaust fan fitted near the roof is the best form, but the portable ones are of considerable value.

We have already pointed out how the effect of fog may be reduced by cutting out all unnecessary illumination. A further improvement may be made by using a lens of

as short a focal length as possible, though not so short as to introduce distortion. Where sufficient length of studio is available, it is now common to use sixteen or eighteen-inch lenses for all-round cabinet work, and it is quite good practice in clear weather. But at other times a ten or twelve-inch lens will be found to give much brighter pictures. As a matter of fact, many photographers have found this out without knowing the reason, and attributed the improvement in brilliancy to some other property in the lens than its focal length. Whatever lens is being used, it should be kept clean. Lenses will get as dirty as windows do in a smoky atmosphere, and will then yield flat images in the clearest light. If a lens has not been kept clean it is interesting to take a negative with it before cleaning and one directly afterwards. In most cases the contrast will be striking. Lenses should be cleaned carefully, a vigorous rub with the corner of the focussing cloth is not to be recommended, as such treatment soon "greys" the surface. An old worn handkerchief, kept in a box free from dust and grit, should be used. If there is a greasy deposit from town smoke, a

single drop of pure alcohol may be applied on a tuft of cotton wool, and then the surface quickly polished with the handkerchief.

Although we are opposed to all "tinkering" methods of development, the judicious use of bromide upon exposures which have been made under adverse conditions is quite permissible. To describe the action of bromide in popular language, we may say that, when used upon an over-exposed or foggily lighted plate, it allows the highlights to get a start before the shadows begin to develop. If the plate be developed right out this advantage is lost, but as most portrait negatives do not reach this stage there is a decided benefit to be obtained by the use of bromide in the cases we have mentioned. It is necessary to add the bromide to the developer before immersing the plate. Once development has started it is of little, if any, effect. The character of the plates used should also be taken into consideration. Some brands tend to give brighter results than others. These should be chosen for foggy weather, as, although the scale of tones may not be so long, the resulting print is more satisfactory.

THE EFFICIENCY OF THE FOCAL-PLANE SHUTTER.

It is perhaps uncommon nowadays to meet with the claim on behalf of the focal-plane shutter that its efficiency, from the very nature of the instrument, is 100 per cent., that is to say, that the shutter admits the full cone of rays from the lens on to the plate during the whole period of exposure. In the early days of the focal-plane shutter, before the optical principles of its action were realised, and while it was accepted as the last word in shutter construction, one found enthusiastic supporters of it, ready to assert that it gave six times the action of light upon the plate in comparison with a shutter of the diaphragm type. Assuming even that the focal-plane shutter possessed an efficiency of 100 per cent., such a statement was hard upon the diaphragm type of shutter, which must be an exceptionally bad one to have an efficiency as low as 16 per cent. However, a recognition of its action, together with experience in its practical use, has shown that the focal-plane shutter, far from being the ideal instrument which it was originally conceived to be, possesses limitations and disabilities apart from its fragility and liability to get out of order which should discourage anyone from over-rating it. Nevertheless, there is probably among some photographers a certain distrust of the criticisms which have been made of the focal-plane shutter in the way of showing the reason for its lesser efficiency in certain circumstances. The idea that a slit travelling immediately in front of the plate should, as a matter of course, transmit to the latter all the light which comes from the lens is one that at first sight appears so readily acceptable that no doubt many people have been inclined to pooh-pooh the figures which have been given, and which may run to as low as 50 per cent. for the efficiency of the shutter. Hence it may be worth while to disinter from the writings of that very lucid and competent French authority on photographic optics, Colonel Moessard, part of the study of the focal-plane shutter published at one of the International Congresses of Photography as long ago as 1901.

Here is Colonel Moessard's diagram, in which O P represents the lens diaphragm of diameter o . Q R is the sensitive surface and A B the blind of the focal-plane shutter having a slit of width a . The distance, e , of the blind from the sensitive surface is shown on an exaggerated scale, for the sake of clearness, but, as will be seen later on, very considerable separa-

tion of the two is commonly met with in focal-plane cameras. The distance, f , is the focal length of the lens, the latter for the purposes of the present study being assumed to be working at infinity. Well, supposing the slit, travelling in the direc-

Fig. 1.

tion of the arrow, to have reached a point shown in the diagram, let us draw lines from the margins of the lens diaphragm O P to the edges of the slit and continue them till they meet the sensitive surface at the points E, F, G, and H. Then it will be clear from a glance at the diagram that the only portion of the sensitive surface which receives all the rays coming from the lens is that which lies between F and G. The portion E F receives rays from the lower part of the lens and the portion G H from the upper, the slit giving rise to a kind of vignetting action. Now the question which arises, which is of great practical interest and which is very clearly worked out by Colonel Moessard, is the production (from this diagrammatic representation) of a formula by which the efficiency of a shutter can be calculated when the necessary constants, namely, the relative aperture of the lens, width of slit, and the distance of the blind and plate are known. The reader must bear with a very little geometry in following the working out of this formula.

As the basis of it we take the common definition of shutter-efficiency, namely, the ratio of the time during which the whole aperture of the lens transmits rays to the plate—the ratio of this time to that during which the lens is uncovered to the plate at all. Now it will be seen from the diagram that for each band of plate which is exposed the action consists of three parts. As the shutter slit comes into position the portion G H is first gradually uncovered, the portion F G receives all the rays from the lens and the portion E F obtains those coming from the lower margins, these being first cut off as the blind continues its course. Thus it will be seen that the covering and uncovering of the portions E F and G H while equal in time are opposite in order. Therefore, one may reckon one only of the two equal times occupied in uncovering the portion G H and covering the portion E F as representing one of them during which all rays from the lens reach the sensitive surface. Now, inasmuch as the blind runs, or is supposed to run, at a constant speed, we can take as a measure of the time which elapses in these successive phases of its action the distances E F, F G, and G H. On the basis just mentioned the period of full action of the lens will be represented by E G and that for the period during which any light at all reaches the particular band of the plate by the distance E H. Thus the efficiency of the shutter will be the ratio E G : E H, and the next thing we have to do is to find a form of this ratio which shall consist of the quantities, viz., the width of

The result of dividing the former quantity by the latter gives the efficiency as compared with 1. To express in percentages, it is multiplied by 100.

An example will make this clear. With a slit-width of $\frac{1}{2}$ in., f/8 lens, and a distance of $\frac{1}{2}$ in. from blind to plate, calculate the shutter efficiency. Here in the formula a the slit-width is $\frac{1}{2}$ th whilst e , the curtain distance, is $\frac{1}{2}$ in. The calculation, therefore, is:—

$$\frac{\frac{1}{2} \times 8}{\frac{1}{2} \times 8 + \frac{1}{2}} = \frac{1}{1\frac{1}{2}} = \frac{2}{3} = .66 = 66 \text{ per cent.}$$

For those who would have some visible basis on which to evolve the foregoing formula a study of a piece of exposition contained in an issue of the *Photo Miniature* of the year 1916 may be commended. The diagram which in our contemporary illustrates this same question of efficiency in the focal-plane shutter is differently marked from that of Moessard, D representing the diaphragm aperture, d the distance from blind to plate, and s the slit-width.

It may be pointed out that by simple geometry the width p of the cone of rays is the curtain distance divided by the F/number. This follows from the two triangles on the bases D and p .

D : p :: f : d . Whence $p = \frac{D d}{f}$. But the focal length (f) divided by the diameter of the stop (D) is the f /number, so that $p = \frac{d}{F/No.}$

Fig. 2.

the slit, the distance between blind and plate, and the F number of the lens.

It is clear from the geometrical construction that

$$E F : O P (= o) :: e : f - e. \text{ That is to say } E F = \frac{e o}{f - e}$$

In the same way, under the geometrical construction,

$$E G : a : f : f - e. \text{ That is to say } E G = \frac{f a}{f - e}$$

Now E H is equal to E G + E F, G H being equal to E F. Therefore, adding the two values just found for E F and E G we obtain for E H

$$\frac{f a + e o}{f - e}$$

$$\text{Therefore the ratio } E G : E H = \frac{f a}{f a + o e}$$

Now, this formula can be reduced to the form we are searching for by dividing numerator and denominator by o . It will be seen that f divided by o is simply the F number of the lens.

$$\text{Thus, after this operation, the formula becomes } \frac{F/No. \times a}{F/No. \times a + e}$$

In other words, in order to find the efficiency of the shutter we multiply the slit-width by the F/No. of the lens; we also repeat this operation and add the distance from blind to plate.

Further, it is easy to establish a rule by which to calculate the efficiency of the shutter under any condition. Remember that the efficiency is the imaginary (calculated) time (T_1) during which the cone of rays is fully operative divided by the time (T_2) during which the cone is operative to any extent at all. Assume that the curtain is moving at a certain speed, t , signifying the time, t , required for it to traverse an inch or a foot—it doesn't matter what the unit is for our purpose. To find T_1 , slide the notched strip (of Fig. 2), representing a slit-width s , along the line of the curtain, and you will see that its passage over p falls into three sections, viz., one on which the full cone is operative, is $s - p$, and two others (at the beginning and end of its transit) in each of which the cone may be imagined as, first, completely covered and then just covered by a slit of width p . Each of these corresponds with the full

action of a slit of $\frac{p}{2}$, so that adding these three sections together, we have $(s - p + \frac{p}{2} + \frac{p}{2}) t$ seconds as the time

of the exposure during which the full cone is operative, in other words $s t$ seconds. Finding T_2 is simpler. Again, if you run the notched strip over p you will see that it is uncovered (wholly or partially) over a length $s + p$. Hence the time, T_2 is $(s + p) t$ seconds. And thus the efficiency or the

ratio of T_1 to T_2 is $\frac{s}{s + p}$. This is a very simple formula,

and, although it may not be perfectly correct, since it assumes the blind to move at a quite uniform speed, it allows of figures for efficiency being usefully calculated.

It will be seen from the Moessard formula that the lower efficiency of the focal-plane shutter arises from the fact that, as used in practice, it does not move in the focal-plane. The nearer it is to the latter the smaller will be the reduction of efficiency, even when a lens of large aperture is used. If the blind works as close as one-eighth of an inch to the plate, as it does in a focal-plane film camera, it will be difficult for the

efficiency to fall below 80 per cent. It is also clear from the formula that if the slit-width is large or if the F/number is large in comparison with the distance from blind to plate, the efficiency will also be maintained at a high figure. It is when a narrow slit is used with a large-aperture lens (a low F/number) that efficiency can fall to as low a figure as 50 per cent. Unfortunately, these are the very conditions which arise in photographing rapidly moving objects when the very briefest exposure requires to be given and when, therefore, the operator has need of the highest efficiency in the shutter. It is, therefore, of the first importance that by some means or other the maker of cameras for this purpose should contrive to bring the sensitive material as close as possible behind the plane in which the shutter blind moves. A few examples calculated from figures all of which may be said to come within the range of practical work will give a good idea of the extent to which efficiency can vary in practice and of the factors which contribute to it.

I.—EFFICIENCIES (IN PERCENTAGES). F/4.5 LENS.

Blind Distance from Plate.	Width of Slit.		
	$\frac{1}{4}$ inch per cent.	$\frac{1}{8}$ inch per cent.	$1\frac{1}{2}$ inch per cent.
$\frac{1}{4}$ inch	82	86	98
$\frac{1}{8}$ inch	60	82	95
$\frac{1}{2}$ inch	51	77	93

II.—EFFICIENCIES (IN PERCENTAGES). F/8 LENS.

Blind Distance from Plate.	Width of Slit.		
	$\frac{1}{4}$ inch per cent.	$\frac{1}{8}$ inch per cent.	$1\frac{1}{2}$ inch per cent.
$\frac{1}{4}$ inch	90	96	99
$\frac{1}{8}$ inch	73	83	97
$\frac{1}{2}$ inch	67	86	96

The reader can see from these figures that in using a focal-plane shutter fitted with a large-aperture lens it is always better as regards efficiency to obtain a given exposure by a wide rapidly moving slit rather than by a narrow slit at a lower tension.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

- A Talk About Lighting (Jan. 3).
- The Camera and the Lens (Jan. 10).
- Managing the Sitter (Jan. 24).
- Backgrounds (Jan. 24).
- Studio Exposures (Jan. 31).

- Artificial Lighting (Feb. 7).
- Printing Processes for Portraiture (Feb. 14).
- Studio Accessories and Furniture (Feb. 21).
- The Surroundings of the Studio (Feb. 28).
- Studio Heating and Ventilation (March 7).

THE POSTCARD STUDIO.

At the present time there are many demobilised men who are desirous of taking up photography as a livelihood, either in the small towns or villages of our own country or, more especially, in the overseas Colonies and Dominions. As a large proportion of these intend to make a start by making postcards their principal line, a few directions as to the way in which this may be readily and economically done may be of service to them.

The question of premises naturally comes first, and as I have no knowledge of overseas conditions in this respect I must confine my remarks on this head to Great Britain alone. A shop front seems to be almost essential to success in this class of business, as nearly all the orders will be "chance" ones, that is to say, they will be obtained through the specimens and announcements displayed in the window. If carefully arranged, quite small premises may be made to answer; in fact, I know of one place, a half-shop, the total width of which was eight feet, in which a very nice little business was carried on. The place was planned thus: eight feet or less from the window a partition was erected, leaving a tiny shop in which inquiries could be answered and sitters could wait, a small table and some long seats being provided.

A narrow doorway gave access to the studio, which was about 18 feet deep. On the remaining portion of the partition the backgrounds were fixed, a plain one being nailed to the wood while a scenic one was fixed on a roller so that it could be lowered when wanted. A part of one side-wall was whitened to serve as a reflector, while a Jandus enclosed arc was suspended on the side nearest the doorway. A couple of chairs and a "rock" accessory formed the furniture. A shelf at the further end carrying a few toilet accessories and surmounted by a small mirror served as a dressing-room, and

behind this was the dark room which had originally been the shop parlour. Not only did this tiny place turn out postcards, but quite a considerable number of cabinets of very fair quality. This arrangement may be taken as typical of the shop studio, and it may, of course, be elaborated when greater space is available.

As all the lighting arrangements are fixed, and the sitter can only occupy one position, a great variety of effects cannot be obtained, but postcard patrons are not exacting in this respect, and if one style can be decently achieved it is all that is absolutely necessary. I must not forget to mention that my favourite head-screen is as useful here as it is in more pretentious studios.

The camera and lens should be selected with a view to the special work to be done, and as most cheap postcards are made by enlarging from small negatives, a camera designed for the purpose should be procured. Several firms supply these, and the beginner should not be persuaded to start with an ordinary camera, as the extra cost of full-sized plates will soon eat up any saving which may be effected. It is usual to take four negatives upon the half of a half-plate cut lengthways, viz., $6\frac{1}{2} \times 2\frac{3}{4}$, this size being regularly supplied by most plate makers. The repeating back should be removable, so that full-sized postcard plates or half-plates can be used for groups or a better class of work for which the negatives have to be retouched and printed by contact. For the small negatives a rapid portrait lens may be used, those originally made for stereoscopic work by Ross and Dallmeyer being very suitable. The focal length is about five inches and the aperture $f/4$. These may often be obtained second-hand for about a couple of pounds. A rapid anastigmat, say, $f/4.5$, of similar focal length may be used, but should

be tested beforehand as the definition, although more even over a larger plate, is not always as critically sharp as that which a portrait lens gives over a small field. For full-sized postcards and half-plates, a portrait or anastigmat lens of from 8 to 10 inches focal length, according to the length of studio, will be most useful. A behind-lens shutter of the flap or Packard Ideal type, should be fitted so that it may be used with either lens without readjustment. This may easily be done by fixing a shallow box inside the camera front to allow the lens to project without touching the shutter.

I now come to the dark-room arrangements, of which it is obviously impossible to give any definite plan without knowing the size and shape of the available space. One thing is certain: that the larger the dark-room can be, within reasonable limits, the better it will be for the health of the worker and the quality of the work. No matter how small it may be, as much sink accommodation as can be managed should be arranged for. It saves much time not to have to move one dish or tray out of the way before another can be used. If possible, negative making and printing should be done in separate sinks, for not only can two people work at once, but the work will be cleaner and more uniform. The illumination should be as bright as is consistent with safety, and it will be found good policy to invest in proper safe-lights for the lamps instead of trusting to fabric or doubtful ruby glass. With a medium which only allows red light to pass a much more powerful illuminant may be used and greater comfort in working obtained at the cost of an extra shilling or two. The source of light may be electricity, gas, or oil. If the former be used the ordinary carbon or metallic filament lamps are best, as the light is more yellow to begin with than that of the small half-watts which are now rapidly coming into general use. Incandescent gas is better than the ordinary flat flame, as it is more economical, gives less heat, and is not likely to smoke the red glass fronts of the lamps. If oil be used, the flame should be of fair size and the lantern arranged so as to supply plenty of air for combustion, otherwise the light will be dull and there will be much smoke. Dish development and fixing will usually be found most convenient, as the exposures will have to be developed in small batches. It will be found advisable to use the same kind of developer for negatives and prints, as this simplifies matters, and I would recommend metol-hydroquinone to be chosen, as it gives stainless negatives and has better keeping qualities than amidol. Those whose hands will not stand metol may use Azol with equally good results. Do not allow developer to stand in an open dish when not in use. It should be poured into a glass pickle-jar and stoppered; it will then keep in condition much longer. An acid fixing-bath should be used, as it keeps cleaner and also has a tendency to harden the negative film, the advantage of which I shall presently mention. In while-you-wait studios the washing of the negatives after fixing is necessarily very short, but it should be done as thoroughly as the time allowed will permit. And there is no better way than by allowing a stream of water to flow over the surface. There is a very old device which effects this perfectly. A small wooden board about 18 inches long and a little more than the length of the plates in breadth has a narrow strip nailed down each side to confine the water. At intervals of a little more than the width of the plates pairs of small brass nails are driven in for the plates to rest against. A loop of string is fastened to one end of the board, and this is slipped over the tap so that the board slopes down into the sink, the stream, from the tap will then run evenly over all the plates. If only a

minute's washing be given in this way the negatives will be safe to print from and will not crystallise in the enlarger.

Printing is usually done by means of a small vertical enlarger, which is frequently home-made. It may be described thus:—A long box is fitted to take in its upper part an incandescent electric or gas light, with a piece of ground glass an inch or two below it. Underneath it is a shelf or stage with a central opening, just the size of one of our little negatives; below this, again, is another shelf, in which a rapid lens is fitted so as to come exactly central with the opening in the negative stage, the image being focussed upon a board fitted with guides and mask, fixed upon the bench or any convenient support. The focus is adjusted so that the image fits the postcard, and fixed once for all. A yellow glass flap or slide must be fitted behind the lens to serve as an exposing shutter, and this should be actuated by a cord and treadle, so that it can be worked by the foot and both hands left free to manipulate the strip of six cards, which is slipped under the mask until all the exposures are made. The next negative on the strip is then slipped into position over the opening and the process repeated. A vignetting card may be placed where most convenient, when required. A condenser is not needed for such small negatives, as the area of ground glass evenly illuminated by the lamps mentioned covers them very well.

For contact prints a strip printer should be installed, and care should be taken that the opening allows of a print being made from the full half-plate when required. It should also be capable of holding a vignette card if needed.

Again I wish to emphasise the desirability of using specially made appliances for this special work. The developing dishes should be made of a suitable size to fit the strips, which should not be developed by dragging through a small dish, nor should the developer be wasted by using an unnecessarily large one.

In postcard businesses quite a nice amount may be made by taking orders for enlargements, and a good show of these should be made in the window. If the studio is a "one-man" concern it will probably pay better to get these made and finished completely by a trade firm. If the photographer decides to do his own he must invest in a half-plate enlarger, and if he is lucky enough to have a good basement under his shop it will make an excellent enlarging-room. No opportunity of bringing this branch of trade under the notice of customers should be neglected, and a special price made when an enlargement is ordered at the time of sitting.

From the small strip negatives miniatures for brooches and lockets may be printed by contact and coloured. It is a good plan to make a special exhibit of six postcards, an enlargement, and a coloured miniature all from the same negative, with the price, together and separately.

The postcard artist will not, perhaps, have much time for outdoor work, but in small places he will frequently be called upon to take wedding and other groups, shop fronts, and the like. For this purpose a whole-plate camera should be chosen, as smaller plates can be used when desired. An eleven-inch rectilinear or anastigmat and a six-inch wide-angle lens will be a good selection. This camera will also be useful for copying or other odd work which may turn up.

In conclusion, I would caution the beginner against purchasing cheap lines in cards and other material. The experienced hand may take risks in this way, but the novice should not handicap himself by using materials in which he has not the fullest confidence.

PRACTICUS.

MESSRS. MARION AND FOULGER, LTD., write to the effect that they are afraid the mention of their exhibit at the British Industries Fair in our issue of February 28 may have been read to mean that they were merely exhibitors of another firm's goods. We are glad to

correct that impression by making it clear that all Messrs. Marion and Foulger's goods are made in their own works, and for that reason were eligible for exhibition at the British Industries Fair, to which only manufacturers are admitted.

A NEW PHOTOGRAPHIC TRANSFER PROCESS.

[The following account of the demonstration at the Royal Photographic Society by Messrs. Middleton and Kent, of the Kerotype Company, of the newly-introduced stripping bromide paper which now appears in the Society's journal, supplements in some respects that which we gave at the time.—Eds. "B.J."]

Mr. MIDDLETON, before proceeding to the demonstration, said that some years ago, while conducting experiments in three-colour photography, Mr. Kent and he found, as others had done, that the great problem was the combining of the three constituent images in correct register. They had also desired to obtain the constituent images by dye-toning a silver one, and so avoid the necessity of printing in daylight. This necessitated the use of a transferred image, and as the carbon process could only be printed by daylight and was otherwise unsuitable, while the other transfer papers, though permitting of the use of artificial light, were somewhat troublesome, uncertain, and limited in their application, they were obliged to devise a new one.

The bulk of the processes involving the use of transfer and stripping films were devised to avoid the use of glass for negative purposes. The parent of them all for preparing the positive was the collodion process of transfer, which was introduced about 1857. In this the image was prepared by the wet-plate process on a waxed plate, transfer being subsequently effected on to gelatine paper. The converse of this—i.e., coating the collodion on to waxed paper and subsequently transferring on to gelatinized glass for negative purposes—was suggested by Laboureaux in 1878, and in succeeding years many suggestions for a stripping paper were made. In some cases the paper was waxed, in other coated with rubber and other resinous and resinoid materials. Sometimes solvents (aqueous and others) were necessary for release, in other cases the film became detached in the developer or automatically on drying. The underlying idea was to obtain at the finish a gelatine image detached, so as to form in itself the printing negative. Only one of these processes, the Eastman and Walker "Transferotype," survived to this day.

The ideal transfer process, to which none of these others approximated, should be one in which (1) the support was textureless and translucent, so that printing through should be possible without much loss of detail or prolonged exposure; (2) the support was little affected by damp, so that register might be possible of one image on another and yet sufficiently porous to permit of the use of aqueous adhesives to transfer on to non-porous surfaces; (3) the support was without tendency to tear, and sufficiently plastic to admit of transfer on to domed or curved surfaces; (4) the emulsion parted with facility when transferred, and was yet so adherent that there was no danger of frilling or blistering in development or of self-stripping when stored; (5) the prints when made would be capable of being kept before transference for as long a period as might be necessary; and (6) double transfer on to any surface was simple and easy, so as to avoid lateral reversal, which could not be escaped unless "printing-through" was adopted.

A long series of experiments had convinced them that paper impregnated with paraffin wax most nearly fulfilled the first three of these conditions, and they subsequently devised a substratum consisting of a powdery nitrocellulose deposited from an aqueous ethereal alcoholic solution, and this enabled any sensitive gelatinous material to be coated thereon, thereby satisfying the three latter conditions. The full details were disclosed in their patent No. 12,091 of 1915. The paper was prepared continuously, i.e., it was put in as a reel of ordinary plain photographic paper, passed through a trough full of hot wax, and after buffing or calendaring in order to lay the hairs down again while the wax was still warm, was coated with the substratum. This passed through a heated chamber, where the

air was exhausted, and was finally coated with ordinary photographic emulsion in a coating machine.

Mr. Middleton here showed examples of the paper at various stages—plain, waxed, coated with substratum, and coated with emulsion. He said that this paper would be found to have many applications, many novel effects being possible by its use, and the process of so transferring photographs would appeal to everyone owing to its simplicity, ease and certainty in application, the large variety of surfaces, both as to texture and form, upon which the transfer could successfully be made, and the pleasing nature of the results. In addition, many novel colour-toning effects were obtainable, owing to the nature of the support and the fact that this formed no part of the final print.

The paper was treated exactly as ordinary bromide paper, but in order to avoid lateral reversal on transfer it was necessary to place the paper in the frame with its waxed support next the negative, so that the printing took place through the support. The translucency and absence of texture in the support was such that the loss of quality was not unpleasing, but should this slight loss be objected to, and non-reversed transfers without such "printing-through" be required, it was necessary either to print in an enlarging lantern, placing the negative with the image towards the light, or, in the case of film negatives, to reverse the negative in the frame so that the celluloid was next to the sensitive side of the paper, or to resort to double transfer, which he would presently describe.

Kerotype paper, as it was called, was made in three degrees of speed: Slow bromide for contact prints, rapid bromide for enlargements, and gaslight. The printing, exposing, and developing of the paper differed in no way from that of ordinary bromide or gaslight, and as to washing, owing to the impervious and temporary nature of the support, seven minutes in running-water would be found ample to ensure permanency. Care should be taken to see that the prints did not lie closely on one another, if the washing was so restricted. Mr. Middleton here passed round some Kerotype prints and enlargements, and also some strippers with which he demonstrated the pulling off of one or two enlargements.

He then proceeded to show how such prints were transferred on to diverse surfaces. For the large majority of such surfaces all that was necessary for single transfer was a 5 per cent. solution of soft gelatine. For all surfaces which were not cockled or spoiled by damp, he simply wetted the Kerotype print thoroughly, placed a pool of the lukewarm gelatine solution—say, 90° or 95° Fahr.—in the centre of the surface to which transfer was to be effected, laid print in contact, lightly squeezed, and left under pressure between blotting paper for a few minutes and placed to dry. In this fashion he made transfers successively on carbon transfer paper, on wood, on metal and on porcelain, which last, having a domed surface, required a little extra patience in manipulation. In cases where the surfaces would be spoiled by damp, such, for example, as thin plain paper, vellum, satin, and so forth, the procedure was slightly different. In this case it was advisable to make up the gelatine solution with a considerable proportion of alcohol therein and to add a medium of golden syrup or glycerine. It was used just as in the other cases. He proceeded to demonstrate the adaptability of the process, thus modified, to these surfaces, and succeeded in transferring a number of examples, which were passed round among the audience by Mr. Kent.

Coming to double transfer, Mr. Middleton said that this was very little more trouble than single. Two methods were avail-

able, one for use on surfaces impervious to moisture, and the other for use on pervious surfaces. In the latter case a piece of paper was smeared with a resinoid solution of rubber and dammar, or rubber, dammar and elemi in xylol. The solvent was allowed to dry, then the paper immersed in water with the print, squeegeed together, and left under pressure for a while, and hung up to dry. After drying, the original support was removed, the surface moistened with ether-alcohol to remove traces of wax, etc., and plunged into water until the greasiness disappeared. It could then be transferred on to any surface by means of a gelatinous adhesive, but, of course, if the support was not pervious to moisture the gelatine could never dry. After drying, the temporary support was released by xylol.

For impervious surfaces another procedure was necessary, based on one first suggested by Lumière in their three-colour process. Here the print, hardened with alum, was either coated thickly with soft gelatine solution or squeegeed into contact with paper coated with such solution, and allowed to dry, after which the waxed paper was removed, the print moistened with ether-alcohol, and wetted and squeegeed into contact with the impervious or other surface which had been previously coated with gelatine containing chrome alum. He showed an example of this method, in which the transfer had been made on an opal surface.

After pointing out that in order to finish the prints a vigorous rub with cotton wool or a little wax in turpentine would be found to deepen the shadows, Mr. Middleton concluded with a few words about failures. If the print was squeegeed into contact with too much force or if it was attempted to remove the print before it was quite dry, the wax paper would not leave cleanly, but it would be found that vigorous friction with a rag soaked in xylol would remove the portions remaining behind without danger to the film. Occasionally, again, either through careless manipulation or the presence of too much air in the water, air was enclosed beneath the print, and in this case steaming was the remedy. In any case this was useful when the surface was desired less matt.

Brief questions put by various members elicited the following additional information:—

The prints were all toned before being transferred. The process was not intended for three-colour work. Experiments had been made in this direction, and as a paper could not be obtained which was satisfactory for the purpose intended, the present one was evolved. They had abandoned for the present the attempt to get proper colours by toning. It was not very suitable for enlarging negatives, as when transferred on to glass it left a considerable grain. The prints could be transferred on to drawing paper by this method, in the way recommended for transferring to satin. Damping the drawing paper could be carried out in the ordinary way with gelatine. The gelatine was put in the middle, contact was made, and after a light application of the squeegee it was allowed to dry. The

gelatine should be used very weak, a considerable quantity being left on, so that it could "pool down" into the pits of the paper. The transferring could be done on to a very rough paper. There would be no objection to pigmenting by this method, as in the bromide process, but probably it would be necessary to pigment before transferring. This new paper would keep well; some had been kept quite good for four years before printing. The prices were the same as for bromide.

Mr. Middleton, when addressing the Royal Photographic Society, stated that he would publish in his paper a bibliography of the patent literature relating to stripping films. Considerations of space have evidently prevented the Society from publishing this latter, but Mr. Middleton having kindly sent us a copy of his compilation, we are glad to be able to add it to his paper:—

We hope at an early date to be able to publish some notes by Mr. Middleton on the experimental apparatus which can be readily made and can serve for investigation, such as that on which he has been engaged.

PURPLE TONES ON BROMIDE PAPER BY RE-DEVELOPMENT IN DAYLIGHT.

RE-DEVELOPMENT may be applied to bromide prints for two purposes, either as a means of improving the colour of a faulty print or to change the colour of image by altering the form of the silver image.

I gave a formula for obtaining purple tones in the Correspondence column of the "B.J." of February 7, and have received queries from readers who seem to have a difficulty in getting the required colour. Following the formula given I have toned batches of prints and get any colour from red to purple-black by diluting the re-developer and developing in full daylight.

The prints to be toned should be thoroughly washed and bleached in daylight. Let them stand in the washing water in daylight;

keep them moving about in the water face upwards until the image has gained in strength, which should be a pleasing pinkish red colour. Then re-develop with the formula given below, which can be diluted to get the desired colour. As the prints dry darker in tone, development should be stopped before the colour proper, but a little practice will soon show. The prints *do not* require fixing. Some papers may not re-develop with the hydroquinone only; if so, use a very dilute M.Q. developer. Prints developed in the first instance with amidol do not give such good tones as those developed with M.Q. The stronger the actinic light the operations are carried out in the better the result. Then, if after the toning process, you are not satisfied with the colour, no need to waste

a print; well wash it, bleach again, and put it in a sodium sulphide bath, and the usual sepia tone will result, slightly intensified. Gas-light paper does not answer to this process, the only colour resulting is a good sepia tone.

The following processes may be used for the improvement of badly coloured prints, or for toning.

Bleach in one or other of the following bleachers:—

- A.—Potass. ferricyanide 140 grs.
- Ammonium bromide 120 grs.
- Water 10 ozs.
- B.—Copper sulphate ½ oz.
- Concentrated sulphuric acid 20 minims.
- Common salt ½ oz.
- Water 10 ozs.
- C.—Potass. bichromate 90 grs.
- Concentrated sulphuric acid 300 minims.
- Common salt 1 oz.
- Water 10 ozs.

After bleaching, wash in running water from 20 to 30 minutes, then redevelop in one of the following solutions, in daylight, which will be found satisfactory, and certain in action:—

I.

- Metol 45 grs.
- Soda sulphite 130 grs.
- Soda carbonate 270 grs.
- Water 10 ozs.

II.

- A.—Hydroquinone 170 grs.
- Potass. metabisulphite 90 grs.
- Potass. bromide 20 grs.
- Water 10 ozs.
- B.—Ammonium carbonate 1 oz.
- Water 10 ozs.

The following table shows results obtained with the various combinations of bleacher and developer:—

Bleaching Solution Used.	Developer used.	Results.
A	II. (A) 1 part. (B) 1 part. Dilute accordingly.	Deep purple brown, similar to gold-toned P.O.P.
A, B or C	I.	Good black with poor prints.
B	I	Splendid blue black velvety shadows as near a carbon print as possible. Resembles an etching on cream crayon.
C	II. (A) 4 parts. (B) 6 parts. Water 2 parts.	Deep brown, fine colour. Whites very clear.
C	II. (A) 1 part. (B) 1 part. Water 1 part.	Excellent sepia equal to sulphided print.
C	II. (A) 2 parts. (B) 1 part. Water 2 parts.	Very pleasing, light brown tone.

The developer may be used several times until discoloured.

ERNEST MANLEY

DEATH OF MR. WELBORNE PIPER.

It is with very great feelings of regret that we announce the death, on Tuesday in last week, March 4, at the age of fifty-five, of Mr. C. Welborne Piper, for a considerable number of years a member of the staff of the *British Journal*, and one of the leading investigators and writers who have taken the processes of photography as a field of study.

Educated for the profession of architect, in which he practised for some years, a serious illness, when he was about thirty, left him in a state of delicate health, which forbade continuous or active occupation, and for the past five and twenty years, first in the home of his parents and latterly in the rooms which he occupied to the time of his death, he led the tepidly busy life consistent with the rather low measure of physical vitality which

was his fate. Yet, despite this disability, he produced a very considerable volume of work in writing and experiment. For some years he worked with a brilliant friend, the late Douglas J. Carnegie, to the joint researches with whom the now widely used chromium intensifier is due. Piper himself is perhaps best known by his share in the invention of the Bromoil process. He worked out within a very short time the method by which the image of a bromide print can be converted into one retaining greasy pigment in accordance with the strength of deposit, and the formulae which he evolved at the outset long remained the standard method of carrying out the process. Among other researches in photographic chemical processes may be mentioned those on the rate of fixation, on the accelerating effects of additions to the

The late C. Welborne Piper.

hydro bath and on the fogging powers of developers, the latter carried out with Dr. Mees in the laboratories of Messrs. Wratten and Wainwright not long before that firm's amalgamation with the Kodak Co. These are but a few of the many minor processes of photography which he made the subject of experiment and in many of which he effected substantial improvements.

But Piper's chief interest lay in photographic optics, of which, though not a mathematician, he had a profound knowledge, and to which he made a number of contributions—for example, in the investigation of depth of focus, the design of depth scales, the correction of distortion caused by tilting the camera, and the design of apparatus for lens measurements. His "First Book of the Lens," written in 1901, is a treatise which, without the aid of higher mathematics, is the most complete account of the properties of photographic lenses which we have, though its title must have misled many a tyro in the subject.

Of an intensely reserved disposition, Piper had few intimate friends, but for them no more loyal associate could be imagined. He was entirely destitute of what is commonly called "aide," and even we, who, we think, have known him as intimately as anyone during the past ten years, are uncertain whether we have appraised his intellectual gifts as highly as they merited. But we deplore the loss of the most sincere of friends, and, for photography, regret the passing of one whose chief occupation in life was to extend the knowledge of its principles.

MANACLED EXPORT TRADE.

THE two communications printed below reached us within four days of each other. The first is the indictment of the red tape methods of the War Trade Department by Mr. Chas. L. Burdick, the head of a business well known among photographers. The second is a statement by the Department of Overseas Trade, the office jointly administered by the Board of Trade and the Foreign Office, which can be interpreted only as an admission of the truth of the charges against the War Trade Department. Here we have the extraordinary spectacle of one Government department inviting harassed traders to let it try its hand at breaking the red tape with which another Government department is holding back trade with neutral countries. We confess we are highly sceptical of any benefit resulting to the commerce of the country in this way. The incident is surely enough to show that a department which has thus to be interrogated by another body of officials had better be taken over lock, stock, and barrel by somebody who knows its business, and who can do it, before many branches of industry, which flourished before the war and are now reviving are handed over to our commercial rivals in other countries.

I.

I am connected with two manufacturing concerns which wish to renew their pre-war trade with merchants in neutral countries, but are practically prevented by Government restrictions.

It looks as though the purpose of the War Trade Department was to hamper British manufacturers until the Germans have had time to organise and occupy these markets.

I should like to say, to begin with, that the goods in question cannot be used for food or in the production of food; they are not of use as raw material or munitions of war; nine-tenths of their value is represented by British labour.

In one case a consignment of goods (for export to Spain) has been held up by the Government for three months because some precious detail of red tape had not been carried out.

These goods had been accepted by the Post Office (a Government department)—even registered—for despatch to Spain, but are apparently now confiscated. We shall probably lose our customer, which is more important than loss of the goods. A Spanish merchant who cannot rely upon us to serve him will buy from the United States or Germany, or someone who can treat him decently.

Re another line of goods which we wish to export to Norway and Denmark. We are told that we must first get from our customer Merchant Guild Certificates.

As indicating the difficulties under which we are trying to do business, allow me to explain the process.

You have an order, let us say, from Denmark for calculating machines (really coin-counting machines, but I wish to avoid the suspicion of seeking publicity); you ask your shipper if he will take the goods; he tells you that you must first obtain a licence from the War Trade Department.

Your first step is to get the forms—this may take you a week (a Government department always takes four or five times as long to reply as a business house would). You are provided with a booklet referring to a "Royal Proclamation" of May 10, 1917, and 34 amendments, all set out in detail. These are further modified by Orders of Council, October 1, 1918, and further amendments. Then follows a list of goods which may, or may not, be exported, or which may be exported to some countries and not to others. You look for your class of goods in the list. They are, of course, not there. This voluminous list (with two or three appendices) has included in it such things as dari, dhol, and mungo, but not calculating machines. However, you think it will save time to apply at once for a licence, but before you can do this you must get your goods in their boxes, or at least ascertain their net and gross weight and the measurement of the boxes. With this you must give pages of information about yourself and your customer, describe your business, how long established, nature of consignee's business, and other details, as set out in a sheet of instructions of some 2,000 finely printed words.

After you feel that you have some insight into this tangle of

red tape, you send in the application. You then wait patiently for about a fortnight and receive a printed letter (probably filled in by a junior clerk in the Government department) informing you that you must obtain from your foreign purchaser a Merchant's Guild Certificate from the country in which he resides.

So you must write to your customer, confess that England is under blockade as far as trade with neutrals is concerned, get him to go to the trouble of supplying you with the necessary documents, and then begin all over again with the War Trade Department.

This process will probably occupy three months—your customer may lose patience and cancel the order. In any event, he will welcome the German manufacturers of calculating machines, who, you may be sure, will not be hampered by his Government officials.

We are taking back returned Army men and hoping to find places for others of our old employees who enlisted, but shall have to turn them down if these foreign markets are practically closed to us.

CHAS. L. BURDICK.

II.

(From the Department of Overseas Trade.)

In order further to assist exporters to recover their trade in goods of which the export is or has been controlled, and generally to ensure that no openings for trade are lost to British exporters owing to ignorance of existing export facilities, the Department of Overseas Trade, in concert with the War Trade Department, has made arrangements for bringing to the notice of exporters, through the medium of the Press, trade journals, Chambers of Commerce, and trade organisations, and by special notes direct to firms on the "Special Register" of the Department, information regarding changes affecting control over exports.

Firms not already on the Special Register who desire to receive such information direct from the Department may apply for admission to the Special Register to the Comptroller-General, Department of Overseas Trade (Development and Intelligence), 73, Basinghall Street, E.C.2. The annual fee for admission to the Special Register is £2 2s., which includes the supply of the "Board of Trade Journal."

It is understood that, owing to the necessary formalities and consequent delay in connection with the obtaining of export licences, exporters find themselves at a disadvantage when dealing with orders requiring immediate acceptance. The department will, therefore, on request, undertake to ascertain from the War Trade Department and reply by telegram or telephone at the earliest possible moment whether licences will or will not be granted for such orders. In the event of an applicant being promised a licence he will be enabled to deal with the order straightaway with the knowledge that upon application being made formally to the War Trade Department the licence will be granted.

Inquiries should be by telegram rather than by telephone, and should be addressed to "Orders, c.o. Advantage, Stock, London." They should give, in addition to the name and postal or telegraphic address of the applicant, the quantity, value, and description of the goods comprised in the order and the name and address of the ultimate consignee if the goods are destined for a neutral country. In the case of orders from Allied or British territory, or from territory in the occupation of troops of the associated Governments, the consignee need not be stated; the country of destination will, of course, need to be given. A reply of twenty-four words (1s. 6d.) must also be prepaid.

Applicants are requested in their own interest to confine their inquiries to orders needing a very urgent decision, since the fewer the inquiries the more promptly can answers be given.

FORTHCOMING EXHIBITIONS.

April 17 to May 22.—Hammersmith Hampshire House Photographic Society Annual Exhibition. Two open classes. Joint secretaries, J. G. Abrahams, 41, Hamilton Terrace, London, N.W.8; A. H. Page, 12, Lime Grove, London, W.12.

Assistants' Notes.

The Photography of Cats.

ABOUT twenty years ago a photographer living at Ealing came prominently before the public as a photographer of cats; he made them a specialty, just as the late Mr. Thomas Fall, of Baker Street, had some years earlier made a name for himself as a photographer of dogs. But since those charming studies of cats have ceased to come from Ealing no other photographer appears to have made a special study of them. Cats are brought to most studios, it is true, just as babies are, and a photographer may be asked to visit the home of "pussy," but such events are usually looked upon as being just ordinary, and few operators, if any, give a cat more thought—unless it be of the evil variety—than they would give to any other subject.

The picturing of cats appears to attract but little attention. Most of the books about cats are badly illustrated by photography, and to see the best cat pictures of to-day one must turn to the pages of the *Bazaar*, *Exchange*, and *Mart*, the issue of which journal for the first Friday in every month deals largely with cats, and the illustrations given therein are reproductions of the finest photographs of cats one is likely to meet with. The majority of the studies are remarkably good, but as the name of the photographer never appears it is impossible for the writer to give praise to the operators to whom they are due.

The lighting of a cat needs care to bring out the animal's points, but not so much care as is necessary with a human being. A good light and plenty of it is permissible, and, in fact, necessary, because of the brief exposures called for. The most important factor in cat work is the choice of suitable backgrounds, and it is in selecting these that the average operator usually comes to grief. A background can make or mar a picture of a cat, and I am inclined to write down the backgrounds of commerce and as used for ordinary sitters as being useless for the work. The most satisfactory plan is to make a series of comparatively small backgrounds of varying colours using millboard as a base, or, if preferred, light wooden frames covered with cheap calico or similar material. Such background may measure about 60 ins. x 40 ins., a trifle larger if convenient, but certainly not smaller. The material—millboard or fabric—is then distempred. If six or eight backgrounds of different shades are made the photographer can select the colour that will "show up" the cat to the best advantage.

An ordinary table is perhaps the most suitable place or "throne" on which to pose a cat, and a background with a continuous piece (foreground) which can be placed over the table when the background is set up upon it is an advantage, as it prevents the junction between the background and the table showing in the form of an ugly line across the plate, though the use of a large lens stop usually eliminates the division to some extent.

Cats are not so affectionate or as easily managed as dogs, but cats know their friends quite as well as do dogs, though they are not so demonstrative. A cat wandering about a street will often take notice of some people, but not others, and in so doing rarely, if ever, attempts to make friends with the person who dislikes cats. And having such mysterious knowledge it is obviously difficult for a photographer who is not a lover of "pussy" to pose one in an artistic or comfortable position.

The ordinary bulky studio camera is of little use for the work, because of "pussy's" proclivities for wandering about the table and to the edge of the background. The camera to use with ease and comfort is the reflex, and in the hand. Much, however, depends upon the behaviour of the feline "sitter." As regards posing, the operator must use his discretion and bring his artistic training into play; some cats look best standing up, others lying down, the most difficult being a sitting position. Cats when in a strange studio will stand up or lie down more readily than they will sit. Lastly, banish all accessories, such as cushions, etc., from the picture, as many otherwise very fine studies of cats have been spoiled by cushions, mainly because cats are imitative, and will only rest comfortably on cushions of their own colour or one very near to it, and when a cat is thus pictured it becomes a difficult matter to know where the cat ends and the cushion begins—
L. T. W.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, February 17 to March 1:—

- CINEMATOGRAPHY.—No. 4,156. Moving-picture apparatus. D. Boixeda
 COLOUR STEREOPHOTOGRAPHY.—No. 3,833. Stereoscopic natural colour photography. J. Crawley.
 CINEMATOGRAPHY.—No. 4,113. Flicker shutter for cinematograph projector machines. W. Diggie.
 LANTERN-SCREENS.—No. 4,312. Process for preparing canvas, etc., screens for cinematographs, etc. R. Gilpin.
 CINEMATOGRAPHY.—No. 4,121. Means for securing ends of cinematograph films. P. Hindmarsh.
 COLOUR CINEMATOGRAPHY.—No. 4,131. Device for taking and projecting colour cinematography. K. Kamei.
 CINEMATOGRAPHY.—No. 3,831. Cinematograph apparatus. C. F. W., and S. M. Portass.
 COLOUR CINEMATOGRAPHY.—No. 4,053. Production of photographic films in natural colours. T. M. Sanders and R. Wellesley.
 PLATES AND FILMS.—No. 4,390. Photographic plates and films. E. B. Smith.

 CINEMATOGRAPHY.—No. 5168. Cinematograph film printing apparatus. H. V. Lawley and C. M. Williamson.
 CINEMATOGRAPHY.—No. 4526. Cinematographs. R. S. McConnell.
 CINEMATOGRAPHY.—No. 4816. Cinematograph apparatus. W. Detway and Co. and A. Wood
 ROTARY PHOTOGRAPHY.—No. 4653. Rotary photograph printing machines. W. Pickup.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention

AEROPLANE CAMERAS.—No. 121,526 (December 20, 1917). The invention consists in a film camera for aeroplane photography, in which the operations of moving forward the band of film, pressing it in the focal plane, releasing and resetting the shutter and recording the number of exposures are performed automatically.

The mechanism may be contained in a box *d*, Fig 2, secured to a casing *e* forming a roll film attachment which is detachable from

Fig. 1.

or hinged to the camera and has removable ends so that it may be loaded in daylight. As shown in Figs. 3 and 4, a spindle or barrel *a* is mounted in the sides *d'* *d''* of the box *d*, and bears wheels and cams by which the mechanism are operated, the spindle being driven by a worm-wheel *b* from a shaft *c*. The film is drawn across the exposure aperture by mangle rollers *e'* *e''*, Figs. 1 and 2, and is fed to a take up spool *f*. The mangle roller *e'* is driven intermittently by a wheel *h* on the spindle *a* which has teeth

round about three-quarters of its circumference and gears with a wheel *i*, a locking rim *A* extended round the untoothed part of the wheel *k* and one or more locking sectors *k* of the Maltese cross type on the side of the wheel *i* ensuring that the roller *e* is stationary during exposure. Proper meshing between the wheels *k*, *i* may be ensured by the provision of pins at each end of the

Fig. 2.

untoothed part of the wheel *k* which engage the radial parts of the locking sector *k*. The motion of the wheel *i* is communicated to the roller *e* through a wheel *j* which engages a wheel *j'* on the shaft of the roller. The take-up spool *l* is driven through a friction drive from a wheel *o* on the spindle *a*, the drive being through a friction clutch to a wheel *p* having a crank *s* on its

Fig. 3.

spindle which engages a radially slotted arm *s* on the spindle of the spool.

The shutter may be of the focal plane type and may be adjusted in the usual manner for varying the exposure. It is set through the medium of a partially toothed wheel *t* on the spindle *a* which drives a wheel *t'* through a friction drive. A star wheel *w* on the side of the wheel *t'* is engaged by a finger *w'* when the wheels are about to mesh to ensure proper meshing. The shutter is released while the wheels *t*, *t'* are out of mesh by the operation of a cam *z* upon the end of a lever *y* which moves a lever *y'* connected to the shutter release. Alternatively, the shutter may be of the between-lens type and be set and released through Bowden wires from levers operated by a cam or cams on the spindle *a*. The film is pressed against a transparent plate *m* during exposure by a plate *1* which is raised against spring pressure during the film-shift by means of levers 2 and links 3, the spindle

9 and a spindle 6 being connected by means of an arm 7 bearing a pin, and a slotted arm 8 on the spindle 9, and the spindle 6 being turned through a lever 5 by a cam 4. A punch 22 for perforating the film between exposed parts may be provided, and may be operated through a bell-crank 23 fastened at one end to a spring *z* and linked at the other end to a lever 2. Means for indicating the number of exposures made may be driven by a pin 11 or by a lever and cam, and a counter dial may be mounted in front of the pilot's seat when the camera is used on an aeroplane and be

Fig. 4.

operated by a Bowden wire from the camera. Means for stopping the mechanism after each exposure may comprise a pin on the wheel *b* in the path of which a stop may normally project, the stop being capable of being withdrawn when desired by a hand-grip release operating through a Bowden wire. A slipping friction-drive may be arranged between the motor and the wheel *b*. According to the provisional specification, means may be provided for automatically stopping the mechanism when a roll of film has been completely exposed, such as a trip-lever throwing out a spring clutch in the motor drive, or means for breaking the circuit of the current to the motor; the film may be shifted by mechanism which starts its movement slowly and gradually increases its velocity until it attains a maximum, and then gradually decreases; and the shutter may be set by a pawl and ratchet mechanism. Harold Workman, 12, University Gardens, Kelvin-side, Glasgow.

Curing the Smoke Trouble in Flashlight Work.

HAVING to make many flashlight exposures for business purposes all the year round (writes Mr. H. G. Grainger in the "Amateur Photographer and Photography" for March 12), it became necessary to devise some means for trapping the smoke after the powder has been fired, the idea being to confine the smoke in a suitable receptacle and release it later outside the house. The appliance takes the form of a box in which the flashlight can be fired. The box was bought at the grocer's, the measurements being 24 ins. by 16 ins. by 13½ ins. deep, *i.e.*, front to back.

The box is lined with white asbestos, which serves the double purpose of fire prevention and reflecting the light. In the centre of the bottom is a tin box lid for the flash powder, in the middle of which a small piece of touch paper is placed in an upright position. The front of the box is a door hung on hinges, on the inside edges of which are strips of velvet.

At about the centre of the lower edge of the door of the box a brass spring catch is fitted, which works in such a manner when the door falls after the flash has taken place, by engaging its complementary part fixed in the middle of the front edge of the bottom of the box, thereby effectually keeping the smoke inside. The box is then carried into the open air, and, the door being opened, the smoke issues in a rush and vanishes at once.

On a couple of rods of light wood a muslin diffusing screen hangs from the lower edge of the door by a couple of picture rings at the ends. By the use of these rings the screen is detachable, so that previous to the work being commenced the muslin can be soaked in water to obviate the danger of fire.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, MARCH 17.

- Braford Photographic Society. Demonstration. "Gum Bichromate." J. H. Leighton.
- Dewsbury Photographic Society. "Carbon Printing." J. Garalde.
- South London Photographic Society. "Practical Iotensification and Reduction." N. F. Horne.

TUESDAY, MARCH 18.

- Royal Photographic Society. "Finishing Bromide Prints." N. F. Horne.
- North Wiltia Field and Camera Club. "Flower Photography." O. W. F. Thomas.
- Hackney Photographic Society. "Versatility," illustrated by Prints. R. H. Lawton.
- Chelsea Photographic Society. Dark Room.
- Birmingham Photographic Art Club. "Passé Partout Framing." S. J. Ford.
- Manchester Amateur Photographic Society. Ladies' Evening.

WEDNESDAY, MARCH 19.

- Croydon Camera Club. "The Defects and Imperfections of Photographic Apparatus and Materials." J. Walker.
- Denulstern Amateur Photographic Association. Competition Portraiture.

THURSDAY, MARCH 20.

- Liverpool Amateur Photographic Association. "Nature's Fly Traps." F. M. Dawson.
- Brighouse Photographic Society. Y.P.C. Portfolio of Prints.
- Holdenfield Naturalist and Photographic Society. Lantern Lecture, "York." Mr. Dawson.
- Hampersmith (Hampshire House) Photographic Society. "Passé Partout Framing." M. F. Black.
- Rodley and District Photographic Society. Monthly Competition. "Still Life."
- Wimbleton Camera Club. "At the Zoo." J. C. Coffin.
- Tunbridge Wells Amateur Photographic Association. "Here and There." H. Wild.
- Richmond Camera Club. "Personal Practice in Lantern Slide Making." D. Johnson.

ROYAL PHOTOGRAPHIC SOCIETY

MEETING held Tuesday, March 11, Mr. W. B. Ferguson, K.C., in the chair.

Mr. W. B. Appleton, of Messrs. Taylor, Taylor and Holson, read a paper on "Improvements in Lenses for Aerial Photography," in the course of which he laid emphasis upon the importance to the lens maker of knowing the precise requirements of the user of the lens and the particular qualities which were desired. In the early days of the supply of lenses for use on aeroplanes cameras it was explained that the quality on which the Royal Air Force set great store was, in addition to acute definition, a certain "relief effect," which perhaps could best be further described as brilliancy of image. Having that requirement stated to them, his firm were able to study the question, and their researches led them to obtain the wished-for result by a further correction of the coma of the lens. The work done by one of their mathematicians, Mr. A. Warmisham, had made it possible to produce a lens which in its reduction of comatical error had been found by most searching tests to be superior to the Zeiss Tessar. Mr. Appleton here, by means of a very ingeniously constructed model, explained the nature of the production of comatical error in the lens, namely, by the spherical aberration of highly oblique pencils, and pointed out the complexity of the calculations which were necessary for its removal. He showed comparative photographs taken by the Cooke Aviar and the Zeiss Tessar of equal focal lengths and relative aperture, the coma defect of the former at angles of 15 degrees and 20 degrees being very markedly less than that of the latter; and he then proceeded to show the actual performance of the lenses in this respect by means of a projection apparatus. Independent test charts photographed with the respective lenses by the Royal Air Force, in the course of tests of lenses supplied, were seen to agree with these observations; as instancing the high perfection of definition which resulted from the removal of coma, the lecturer mentioned photographs taken at a height of 3½ miles with a 4in. Cooke Aviar in which the presence of barbed wire could be detected.

A further short paper was read by Mr. Hasselkums, of Messrs. Ross, Limited, on the modifications made in the Ross Xpres lens for use in aerial photography. In the standard pattern of Xpres lens the corrections for coma and astigmatism were so made that in using a lens at an angle of, say, 60 degrees the definition in the margins of the field would be somewhat better than in the midway zone. Thus, when such lenses were used at the narrower angle employed in aeroplane photography the less highly corrected portions of the field fell around the margins of the plate. They had, therefore, modified the construction of the lens so as to yield a uniformly high comatical and anastigmatic correction over an angle of 36

degrees. He showed photographs in which the critical definition over this angle was uniform. A second model of lens working at an aperture of *f*/6 was constructed from only two types of glass, and, though limited to these optical materials, the performance, as shown by photographs, was of a very high order.

In a brief discussion, Mr. Conrad Beck referred to the common fallacy that a lens which fulfilled the sine condition was necessarily free from coma. The misconception was due to disregard of the behaviour of oblique pencils. Lieut. Jennings gave some particulars of the photographic camera made in the form of a Lewis gun and of very great value in the training of air pilots in machine gunnery.

On the proposition of the Chairman, the hearty thanks of the meeting were accorded to the lecturer.

CROYDON CAMERA CLUB

MR. G. A. ARDASER, an ever-welcome visitor, last week gave a lantern-lecture on "More Curiosities Seen Under the Microscope," a title, he said, which was an improvement on the one sent to the secretary. Curiosities, of course, need not be microscopic, and, if memory serves aright, the "Walrus" once defined the members as a weird collection of human oddities. True, at the time he happened to be under sentence of death by boiling oil for making an unfortunate mistake in the day on which the weekly meetings are held, and this may have coloured his vision. As pointed out by a member, perhaps the only thing appertaining to the club which might repay microscopic examination in its reputation, but the high power required introduces difficulties hardly worth encountering with success so problematical.

"Curiouser and curiouser" cried the immortal "Alice in Wonderland" when she found herself "opening out like the largest telescope that ever was." What she would have exclaimed may be left to the imagination if she had seen the leg of a dragon fly the size of a tree trunk, not to mention the many other tiny people and things "opened out" by Mr. Ardaser. And little Alice would have understood quite well his delightfully clear explanations of the superb slides shown, for he does not believe in associating a dead language with the depicted defunct unless compelled. For instance, when differentiating between diatoms, instead of the usual terrible identification labels, what could be happier or clearer than pointing with the stick to that "triangular bloke there."

Without doubt the most interesting slides illustrated the daffodil disease, which in one district alone caused a loss of £150,000. It does not confine its ravages to daffodils, but extends to other plant and vegetable life, and can be starved on barren soil for five years and come up smiling at the end of the fast. When the lecturer was approached by the Royal Horticultural Society to investigate the matter, little more was known beyond the fact that minute worms were the cause of the trouble, and it was only after close study for a long time that their life habits were revealed by this Sherlock Holmes of the microscopic world. No cure has as yet been found, but it is to be hoped that some bacteria will be discovered with a fine appetite for this particular spread.

One little marine insect shown Mr. Ardaser said he approached with some diffidence, as its habits were extremely bad, and its name was "Harper." Eventually it lost its tongue. "Then it is certainly no connection with our 'Harpur,'" emphatically observed a member, and the lecturer looked relieved. Dealing with succulent slugs, who are almost exclusively vegetarians in fact, and also to aspect, for they hardly look like beasts of prey, he said one variety, usually killed by gardeners, is their best friend, for it devours worms and other pests. A most hearty vote of thanks was accorded Mr. Ardaser for a lecture listened to with intense interest. His way of starting with "Gentlemen, including the President," is a neat method of escaping the invidious inference contained in the customary formula.

Friends of Mr. A. F. Catharine (past President) will learn with great regret that, from the symptoms described, his favourite dog is undoubtedly suffering from the daffodil disease.

MIDLAND RAILWAY INSTITUTE PHOTOGRAPHIC SOCIETY.—At the annual general meeting on Monday, March 3, the President, Mr. W. N. Bancroft, in the chair, the annual report and statement of accounts were adopted, the latter showing the society to be in a

ound financial condition. Officers for the coming season were elected as follows:—President, Mr. J. E. Anderson; vice-presidents, Messrs. R. W. Reid, F. J. Greasley, and T. Ward; hon. sec., Mr. C. Gadaby Thorpe; hon. treasurer, Mr. T. A. Luxford; hon. auditor, Mr. J. J. Hennessey; Committee, Messrs. Bell, Caulkin, Pegg, Dallman, and Hammersley. Mr. H. C. Cross, secretary of the Leicester Photographic Society, then gave his lecture, "Holidays in Derbyshire and Devonshire," which, with its accompanying lantern slide illustrations, was very much enjoyed. A hearty vote of thanks was accorded to the lecturer. Mr. R. W. Reid then proposed a vote of thanks to the retiring president. He said Mr. W. N. Bancroft had been president of the society since October, 1917, and though there were many other claims on his time, he had maintained a keen and helpful interest in the society. All would regret Mr. Bancroft's retirement, but in Mr. J. E. Anderson he would have a very able successor who had always been active for the society's good since its inception. The hon. secretary seconded Mr. Reid's proposal, and the vote of thanks was passed with much enthusiasm. There are now 170 members of the society, an increase of ten during the past year. Upwards of forty members have served with his Majesty's Forces in the war, and three have made the supreme sacrifice. A Roll of Honour is being prepared and will be hung in the Institute. The Hon. Secretary announced that efforts will be made to revive the summer excursions and the annual exhibition, and for the next winter session it is hoped to arrange some evenings for the benefit of beginners in photography, in addition to the usual lectures and demonstrations to be provided.

Commercial & Legal Intelligence.

NEW COMPANIES.

DONCASTER ROTAPHONE Co., LTD.—This private company was registered on March 5 with a capital of £2,000 in £1 shares. Objects, to carry on the business of and employ, as far as possible, the shareholders in the company in producing by mechanical and other means, photographic view cards, birthday and other cards, photographers, etc. First directors:—W. A. Roelich, 18, Oxford Place, Doncaster, photographer; J. Simonton, 27, Young Street, Doncaster, photographer; and B. H. Gray, 3, Hall Gate, Doncaster, law student. Registered office, 6a, St. George Gate, Doncaster.

News and Notes.

SILVERING MIRRORS.—Writing to the "English Mechanic," Dr. Charles C. Godfrey, of Bridgeport Conn., gives the following directions for silvering glass, by the Lundin method:—

(1) Make a stock solution of nitrate of silver which shall contain 5 grains to each fluid drachm of distilled water.

(2) Make a stock solution of pure formaldehyde which shall contain 10 minims to each drachm of distilled water.

(3) Make a saturated solution of chloride of tin (pure stannous chloride) in distilled water.

Determine the amount of fluid necessary to cover the surface of the mirror when in the silvering dish to a depth of $\frac{3}{4}$ in., silvering face up.

Use 2 drachms of the stock silver solution and 2 drachms of the stock formaldehyde solution to each fluid ounce of the required amount of silvering solution as thus determined.

Having removed the old coat of silver with nitric acid and washed the surface, take a large wad of surgeon's cotton soaked in chloride of tin solution and rub the surface of the mirror thoroughly with it, then, holding the mirror under a stream of water, continue to rub until all the tin chloride is removed from both cotton and mirror.

Now cover the mirror, in a dish, with water about 20 deg. F. warmer than the temperature of the air. Ordinary water from the tap will do.

Prepare the silver solution in the usual way with aqua-ammonia until the precipitate formed is nearly dissolved, and add water to make one-half the required amount of silvering solution.

Take the requisite quantity of formaldehyde solution in another

vessel and add water enough to make the other half of the required solution. Now place the mirror in the silvering dish. Mix the silver and formaldehyde solutions thoroughly, and quickly pour over the surface of the mirror.

It is not so necessary with this method to have distilled water as with the potash method. Rain water, or, in many localities, surface or reservoir water, will do as well, but it is advised to try it out on a small scale first to see if the water is suitable.

I believe that the use of the chloride of tin is to remove any film of oil or grease which may be on the surface of the mirror which it does beautifully and leaves the surface so that it remains wet all over when stood on edge.

It is essential that all tin chloride be removed from the mirror, however, or the silvered surface will be mottled.

I find a cheap pair of rubber gloves prevent soiling of the hands and preserve the surface of the mirror from finger marks.

Mr. Lundin surrounds his mirrors with a band of heavy bandage soaked in beeswax and tied on. This prevents any portion of the mirror being silvered except the surface. This causes some saving in the quantity of silver required, but as this is not a heavy item where one mirror is to be coated, I prefer the usual method of using a dish slightly larger than the speculum, coated with paraffin wax. Besides, it is claimed that a mirror retains its figure better with changing temperature if silvered all over. Always silver with the face of the mirror up.

I am under the impression that the silver surface thus produced is harder and more durable than that produced by other methods, besides not requiring quite as careful manipulation.

Correspondence.

CINEMATOGRAPH OR KINEMATOGRAPH.

To the Editors.

Gentlemen,—I question whether Mr. Lockett is right when he says it is the general rule in English words derived from Greek beginning with or containing *k* to convert *k* into *c*, although in these words which have come from Greek through Latin the change no doubt is sometimes made. But it is not a matter of spelling only; it is also one of pronunciation. Many Greek-derived words, when spelt with *c* are pronounced *k* (camera), while in some the *c* is soft (centre), both of which come from Greek through Latin. There is no rule.

But there are several words which come direct from Greek in which the *k* is not converted; Kilo, kaleidoscope, katabolism, kerosene, and (more to the point) kinematic and kinetic. These last two were established in the language before the word in question—which is compounded from them—was required, and to prove only patriotism seems hardly an adequate reason for departing from its proper spelling; or, if it must be spelt *c* out of politeness to our Ally, for the cacology of pronouncing it *s*.—Yours truly,

Epsom, March 8, 1919.

TRAVERS J. BRIANT.

PHOTOGRAPHY OF THE ROYAL ENGINEERS.

To the Editors.

Gentlemen,—It was with interest I read of the doings of the R.E.s in the great war. May I, however, be permitted to add another branch of photographic work carried out by that magnificent corps which is not known at all by the general public, if even in the photographic world. I refer to the taking of photographs recording progress of such huge works as the construction of the train ferries now running so successfully between this country and France, the construction of that new Kent port of Richboro, numerous aerodromes, and last, but not least, the National shipyards at Chesham, Beachley, and Portbury.

It was my good fortune when in khaki to be actively connected with that work. To record progress weekly of such huge works has entailed a gigantic amount of work and skill. The demand of the big folks up in London to see the actual progress at intervals was no better portrayed than by photographs. The work of taking

these photographs has often rested with one or two men at each job, and the difficulties in obtaining suitable accommodation have at times been enormous. Barren spots devoid of houses, water, artificial light meet the photographer on his arrival. Still, the photographer has to get to work before the actual progress starts, to show what the place was like to commence with, and despite all these drawbacks, photographs have to be taken, developed and printed on the spot and despatched quickly to H.Q. Together with the carrying of equipment, generally a 12 by 10 outfit, the climbing about to get advantageous positions, makes the lot of the photographer by no means a pleasant one to commence with. With time, however, conditions improve, and the work of recording the progress becomes more and more interesting.

As your correspondent remarked, the Air Force has got all the plums, but, after all, the R.E.A. have done an enormous amount of work, and have done it well, too.

FRANCIS H. STOKILL.

THE ASSISTANT QUESTION.

To the Editors.

Gentlemen,—As the present correspondence on this subject has the appearance of closing, through lack of interest, I should like to add one or two observations before the end comes.

Reviewing the whole matter broadly, I believe there are many who will welcome the disappearance of this topic from the columns of your interesting paper. No doubt there are many employers who honestly would be sorry if any scheme for the standardising of efficiency, as applied to assistants, came into vogue. Also there are many assistants who have no keen desire to train or to qualify further.

The reasons for these attitudes are quite apparent, and, stated roughly, are as follow:—Those employers either do not want skilled assistants, or they do want them at the price of unskilled labour. Those assistants believe that a union of photographic assistants would secure to them all the advantages of self-advancement without any personal effort or achievement.

The opinions and suggestions of assistants who wish to secure advancement by merit are, I believe, being collected by Mr. Marcus Adams. Are the employers who require the services of such assistants giving him the necessary support to enable him to form a basis for a clear scheme? Of course, there is no definite indication that they are prepared to entertain seriously any scheme at all, and one can only hope that Mr. Adams will not labour in vain.

Glancing again over this correspondence, I think employers have contributed very little sound matter to it. The letters of those who have contributed are not convincing, and not one has clinched his points. If assistants are declared to be inefficient, it is surely time that proof be established, and we all know where we are. It is not just to me, who are assistants, to have our abilities submitted to a test which is individual, variable, and evidently ethereal. If there is no recognised degree of efficiency to be attained, it should not be a matter for complaint that it is lacking. An unwritten law of efficiency is neither desirable or practical.

Inefficiency in some applications is undoubtedly an economical abstract. I do not apply that generally, for I know that in photography to-day there are people who lack even elementary knowledge. But they are there, and they live. Yet the responsibility for those people does not rest with assistants. Similar disasters might overtake chemistry, engineering, or even banking, if employers and associations became lax and apathetic.

Undoubtedly unless firm action is taken, at some not distant period, photography as a profession will cease to exist. Skilled assistants will become an unknown quantity, and the future masters of the photographic art will be created for the unskilled assistants of to-day.

To demand skill and to recognise it is to build up a profession, which will be able to pay salaries in accord with its claims as a profession. Without that demand for skill and its recognition, a union of photographic assistants, irrespective of skill, is bound to come as the only means of securing a living wage. Those two ways of advancement I commend to all who think seriously, if they are worth consideration.

Thanking you for your courtesy in publishing these letters.—
Yours truly,

ROWLAND SAMME.

Reigate, March 4, 1919.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

POSTCARD.—If of late pattern, with outside diffusion adjustment, about £13.

G. C.—This apparatus came largely from America, and now, in common with other photographic goods, is among the prohibited imports. We should think your best chance of getting one would be from one of the secondhand dealers.

J. C.—We are afraid that your description of the two Clement and Gilmer lenses is still a little vague. We should say that the shorter focus lens is one that was sold as a half-plate and the other as a large cabinet or whole-plate. It is difficult to estimate the value, but we have lately heard of one of the larger size being sold by a dealer for £5, and the other would, we should say, in like proportion be worth about £4. We think you should have no difficulty in getting three guineas for the aerograph.

V. E.—Addition of acetic, nitric, or oxalic acid destroys more or less the setting qualities of the gelatine, and thus renders the gelatine more soluble. But, of course, by treating it in this way you reduce the setting properties of the jelly. We know of no way of increasing the solubility of the gelatine without doing this. You might try several small additions of chloral hydrate, but we think that with this also you destroy the jellifying property. The maker of emulsions usually does what you seem to have in view by mixing soft and hard gelatines together.

T. S. STEWART.—The fixing bath which is the most rapid in action is one containing 8 ounces of hypo per 20 ounces of water, together with some ammonium chloride. The quantity of the latter is not very material, but one to two ounces would be sufficient. Except for the greater speed with which the emulsion is dissolved out of the plate in the first instance, there is no advantage in the use of fixer containing ammonium chloride: on the other hand, it is possible that a bath of this kind, as it becomes exhausted, acts less satisfactorily than one containing hypo only.

G. H. B.—The best firm in the portable studio trade is Messrs Boulton and Paul, Norwich, but it is very doubtful if they can supply at the present time. You might try having the studio made locally if you can find a builder who does not speak of wood as though it were gold, but we should certainly think that your best chance of getting a studio at a moderate price would be through a small advertisement in our columns. With the progress of demobilisation of camps in this country we imagine that there must be a fair number of these studios changing hands.

F. P.—For extremely fine grain it is necessary to use the finest grade of carborundum powder, such as you can buy from Messrs George Adams, 255, High Holborn, London, W.C., but even this will not be sufficiently fine for your purpose until you have got rid of the coarser particles in it by stirring up in water, allowing the coarser elements to subside, then pouring off the other and allowing the fine carborundum to settle. 2 Ply wood can be

bought in small quantities from any of the depôts of Messrs. Hobbies, Ltd.; the address of one is 65, New Oxford Street, London, W.1.

B. B.—You will certainly find the half-watt lamps simpler in use than the arc, and we should say that four 500 c.p. lamps will do all you require. These should be fitted with reflectors so as to throw all the light possible upon the white screen. It is very necessary to run the lamps at their full voltage to secure an actinic light. A slight drop in the voltage hardly affects the visual value, but may increase the exposures by 25 per cent. Have you looked into the question of using the "gridiron" pattern of mercury vapour lamp? This illuminates the negative by direct light, and is much in favour in the United States. It is made by the Cooper Hewitt Westinghouse Co., 80, York Road, King's Cross, London, N.

C. L.—The only book of instruction in collotype is "Photo-Mechanical Processes," by W. T. Wilkinson, price 4s., from Messrs. Hamptons, Cursitor Street, E.C. But it would be impossible to qualify yourself for practical collotype work merely by learning the subject from a book. You would require a course of practical instruction such as is available at the L.C.C. School of Photo-Engraving, Bolt Court, Fleet Street, London, E.C. After such a course, the working of the process should not be beyond the capacity of anyone of reasonable photographic experience.

P. B.—We have no opportunity of discovering the precise formulae you seek from the "Photographic Bulletin," but the customary method of sensitising silk is first to immerse it in a solution of salt and gelatine. The Iceland moss which you mention is an alternative to the gelatine, which does not possess, so far as we know, any appreciable advantage. The solution is:—Water, 10 ozs.; common salt = sodium chloride, 100 grains; gelatine, 20 grains. This solution is made with the aid of heat, and, after saturating the silk, the latter is stretched on a frame and, when dry, brushed with a solution of silver nitrate, 40 grains to the ounce. After again drying, it is ready for printing.

J. E.—1. A licence is necessary from the Ministry of National Service for starting a new retail business, but we think you will have no difficulty in obtaining it. You require to write to the Director of National Service, 84, Westbourne Terrace, Paddington, N.W. 2. No reason whatever why you should not call your studio the "Royal" providing you do not display any sign resembling the Royal Arms. 3. Photographers' studios are subject to the provisions of the Shops Act so far as concerns the studio and parts of the premises where the public are received. The Act itself provides no limit as to the lateness of closing, but makes it compulsory to close the studio for one half-day in each week.

ARTIFICIAL LIGHT.—I am about to commence a photographic business, and would be much obliged to have your advice on the lighting of my studio, the size of which is 16 ft. x 7 ft. I can only use artificial light, and intend to have half-watt lamps. Can you tell me the candle-power and number of lamps required, and in what position to place them? As I have only 7 ft. across the studio, does this distance allow for a good lighting effect for taking portraits up to cabinet size?—B. H.

The width of your studio is so small that it is difficult to say what would be the best arrangement, but we have found a single Westminster arc lamp to answer well in one nearly as small. Either that or two 1,000 c.p. half-watt lamps should be sufficient if placed near the wall about 6 ft. from the background and 7 ft. high. Use thin white calico as a diffuser and if possible a circular head-screen.

T. A.—We quite agree with you in trying to do without flash-light, but if the studio is at all on the small side you are under the difficulty, when using gas alone, of making it very hot if it is necessary to keep the light burning for any large proportion of the time. On the other hand, when using flash powder, you have the drawback of generating smoke if much use is made of the lamp. There are two good lamps—the "Hewellite," of Messrs. J. J. Griffin and Sons, Kingsway, W.C., and the "Powerful," of Messrs. Kodak, Ltd., Kingsway, W.C. There is also a combined flash and gas lamp made by the Tress Company, 4, Rathbone Place, Oxford Street, W.1. The only other

alternative, apart from the electric light installation, which would cost probably anything from £200, is the paraffin mantle lamp of the Blanchard Oil Lamp Co., 151, Farringdon Road, E.C.1, but if you can get gas there is little reason for considering this latter.

C. O.—1. Assuming that you will not work larger sizes than whole-plate, and that the bulk will be cabinets, we should recommend a lens of 12 or 13 ins. focal length with a maximum aperture of $f/4$. Ross No. 3 cabinet, Dallmeyer 2a, or perhaps 3b (this is about 11 in.) or a Cooke Series II.a 12 in. The prices of such lenses now range from about £18 to £25. If obtainable secondhand, they will cost about 25 per cent. less. Lenses of less well-known makes may be picked up at a dealer's for £7 to £8, but these should only be bought after testing. 2. With regard to a studio camera, we can only refer you to makers' catalogues, and, after consulting them, we are afraid you will find some difficulty in getting a new instrument. The second-hand dealers can sometimes supply, but just now there is a dearth of studio cameras and lenses. Messrs. Watson and Sons and Marion and Co. list excellent models, while American styles can be seen at Messrs. Kodak's, Kingsway, and the Ansco Co., 143, Gt. Portland Street, London, W.1

C. E.—1. We recently put your query to a manufacturer, and he said Nature herself cannot make colours to stand the bleaching action of light. Pigments or mineral colours mellow down. Although improvements are being made and research work is keen, no manufacturers will give a guarantee with a particular dye that it is absolutely permanent for all time. For your purpose there are about twelve excellent colours classed as "fast" to light. These have been and are most largely used for colouring. Dyes sold in packets for cotton and woollen goods are not so suitable as those selected for gelatine. 2. "Dark blue and black water colours" we presume refer to Antwerp or Prussian blue and ivory or blue-black, which, being transparent, require a homeopathic dose of Chinese white to give them body or covering power. You will also have to stipple the colour to get the modelling required and hide the sepia base. If you are using Seltona paper, it saves time afterwards to paint a blue dress or a black coat with strong salt solution before fixing. You do not state the make of paper, but we gather by the word "take" your paper is greasy, in which case ammonia water, oxgall, or quillaia will correct it. Glycerine and alcohol is helpful for some papers. Varnish with this, let dry, and apply your tints. For glossy collodion papers try varnishing with a mixture of borax and gum arabic, or for dye work size the print with $\frac{1}{4}$ oz. gelatine in 5 ozs. warm water, allow to harden, then work on that. Further useful hints on colouring are given in "B.J.A.," 1919, pages 297 to 301.

SUMMARY.

A note of the successive changes in plate prices will be found on page 149.

Photographic goods, including plates and papers, may now, so it is announced by the Board of Trade, be exported without licence to all non-enemy destinations. (P. 144.)

An account of the successive patterns of camera which have been employed in aerial photography by the Royal Flying Corps during the course of the war is contained in an article on page 139. A changing mechanism actuated by a propeller on the aeroplanes, and a film camera operated by similar means, are among mechanical devices which worthily rank with others of the war.

At the Royal Photographic Society on Tuesday evening last a most admirable demonstration of the finishing of bromide prints by working up with Comé crayon powder was given by Mr. Newman F. Horns. (P. 146.)

A list of the premises connected with photographic and allied business which were damaged during the air raids on London is given on page 143.

In a leading article we deal with a few of the considerations which ought not to escape the constant thought of every master photographer—namely, three which make for hygienic conditions in work-shops. (P. 137.)

In this week's article "Practicus" deals with the equipment of the professional photographer's printing room, unobscuring the advantage of very ample accommodation in the way of sinks. (P. 140.)

Some peculiarly choice specimens of the cadging letters written by photographers adopting the system of promiscuously offering free sittings are contained in part of an article which we quote from our contemporary, "The Advertiser's Weekly." (P. 143.)

The assistant question comes in for some more than ordinarily thoughtful consideration this week in the shape of the article on page 142 and letters on page 150.

A characteristic tribute to the late Mr. Welborne Piper is part of the report of the Croydon Camera Club's meeting last week. (P. 143.)

Some of the precautions which continue to be brought to our notice as necessary for the safe packing of a negative transmitted by post are the subject of a paragraph on page 138.

Much of the vibration of a camera carried on a push-bicycle or motor cycle can be avoided by laying a thick strip of felt on the cycle carrier and a similar piece at the bottom of the camera case. (P. 138.)

On many occasions, particularly in interior work, advantageous use may be made of a flash-lamp or flashpowder, as auxiliary light-
ing. (P. 137.)

EX CATHEDRA.

Cheaper Plates.

It is announced that the prices of dry-plates have been reduced as from March 11th last. The reduction brings quarter-plates to 3/- per dozen, half-plates to 6/6, and whole-plates to 12/3. Taking the quarter-plate as the basis of comparison it will thus be seen that the reduction to 3/- from 3/8, which was the figure reached at the last rise on August 1st, 1918, amounts to a fraction over 18 per cent. The present price of the quarter-plate, in comparison with the pre-war figure of 1/3 per dozen, is still 140 per cent. higher. The schedules issued by the plate-makers give the complete figures of prices for extra rapid and ordinary plates, panchromatics and X-ray plates in both the English and metric sizes.

Supplementary Flashlight.

Photographers as a whole are not fully aware of the advantages that flashlight has to offer as a supplementary illuminant when making exposures under difficult conditions. It sometimes happens that a certain amount of day or artificial light is available by which the exposure has to be made—that is, insufficient of itself to light certain portions of the subject sufficiently for them to be fully exposed before the more brilliantly illuminated parts were hopelessly over-exposed. It is under conditions like these that the flash-lamp, which need only be of a simple form, or which may even be dispensed with if the prepared powder, such as Johnsons, is employed, becomes of real assistance in solving the difficulty. We may, in explanation, cite an instance of this which occurred in our own work some years ago. The subject was an interior of an ancient abbey, the building badly lit through stained glass windows, two of which were directly facing the camera. The details of these windows, which were, of course, fairly well illuminated, were required in the negative together with a good rendering of some dark oak choir stalls in the foreground which were very badly illuminated indeed. A plate was exposed by meter for the windows, and just before this period was complete a strong flash was fired, sufficient to illuminate the whole of the interior. Careful development produced a negative that was "just right" for its purpose. The flash should be fired almost at the end of the exposure; if this is done before, there is a tendency for the smoke from the flash to cause a belt over the picture. The above indicates some simple means of overcoming difficulties due to bad illumination, and may be noted by commercial photographers who often are expected to produce first-class results under very unfavourable conditions of lighting. Some may be inclined to adopt the usual reflector and diffuser in connection with the flash, but though this may at times be desirable when dealing with very irregular

lightings, we prefer to increase the flash in strength and keep further away from the subject if the building will admit.

* * *

Packing Negatives. Even in such simple matters as sending a negative through the post there are pitfalls for the unwary of which anyone to whom negatives come is being constantly reminded by the receipt of parcels of glass shattered to atoms by the thump of the post office stamp. Enlarging firms who would caution their customers ought to arrange for them to visit the sorting floors of a big postal depot. It would provide a salutary warning against packing negatives between pieces of card or with no greater protection than the cardboard plate box in which they travel at the risk of their lives. Now that so many pursue the photographic process no further than the making of the negative the safe transit of the developed plates to the enlarger is as important an item of after-treatment as intensification, yet many people seem not to know that to make perfectly sure of its safe arrival the negative should travel in a wooden box so that the walls keep the shock of the defacing stamp off it. If it be prevented from shaking about in the box by cotton wool, wood shavings, or even crumpled paper above and below, the sender may challenge the Nasmyths of St. Martin's-le-Grand to do their worst. One other little precaution should be noted. If several negatives of different sizes are being sent together they should be placed so as to prevent the smaller bearing unevenly on the larger. For example, a quarter-plate should not be sandwiched between two half-plates, but be laid upon them with a piece of card between.

* * *

Field-Camera and Cycle. Those photographers who reside in country districts and have occasionally to carry a heavy field camera and tripod upon a cycle realise that if care is not taken such means of transit are likely to have a very detrimental effect upon their apparatus. The best place for the camera case is without doubt upon a strong back carrier firmly secured to the machine, though some workers have a preference for the front carrier. In the latter position there is a greater tendency for the camera to be shaken about, while if a proper carrier is not used there is a certain strain upon the sides in guiding the machine, especially if the instrument is a heavy one. Even on a back carrier there is a tendency for the case to get badly rubbed, and even the instrument itself may be scratched if a little care is not taken as a preventive. Some time ago, after a cycle journey of some miles across badly made roads, we had the experience of a camera case rubbed right through by the vibration between it and the cycle carrier, together with a broken plate in the dark slide, which necessitated a further journey for the purpose of making another exposure. Since then we have prevented such trouble ever recurring, very simply, in the following manner. A couple of strips of felt about two inches in width and about an inch in thickness, such as may be bought for a few pence at any saddler's, is placed at the bottom of the camera case for the instrument itself and slides to rest upon, and another strip of felt is laid upon the carrier before the case is put on. The felt will absorb some vibration, and the troubles detailed above will not be encountered. We have also adopted this idea when travelling on a motor cycle, when it is equally successful. The best place for the tripod is across the handle bars or along the top tube of the cycle. Such a plan is far better than slinging the case upon the operator's back when, if the instrument is a heavy one, its weight is soon felt.

A QUESTION OF HYGIENE.

THE recent epidemic which we have called influenza, because we know of no better name, has robbed the photographic profession of some of its best known members, while others, happily recovered, have suffered severely from it. As it is well known that the disease is most likely to attack those whose vitality has been impaired by any cause, it is worth while considering the conditions under which many photographers work.

Comparatively few photographic businesses are carried on in premises built for the purpose, and in contriving accommodation for the various branches of work there is often overcrowding and poor ventilation, both of which are inimical to health. It is, perhaps, in the dark-room that the worst conditions prevail, and now that bromide paper is so universally employed for printing, a much larger proportion of the working-day is spent therein than was the case when daylight printing was almost exclusively the practice. In excluding white light from an ordinary room there is always a great risk of excluding air as well, and, unfortunately, few dark-rooms are so contrived that when not actually in use they can be thrown open so that light and air are freely admitted. For it must not be forgotten that light has a purifying effect equal to, if not superior to, fresh air. In many cases the door forms the only source of ventilation, and, when closed, the unhappy operator has to breathe the same air over and over again. A good many years ago we were consulted with regard to a dark-room lamp which the purchaser declared was faulty, as, after being lighted for a few minutes, it commenced to smoke and gave practically no light. The dealer from whom it was purchased tested it in his shop and pronounced it to be in good order. This was also the case when we tried it. Finally, we ascertained that the dark-room was only about six feet square, and that it had a well-fitting door, so that "the light that failed" did so through lack of oxygen. If an electric bulb had been used instead of a paraffin lamp the question would not have arisen, but the operator's health would certainly have suffered. We have seen in a prosperous West-End business a dark-room which could only be used by opening the window for a few minutes after developing each set of plates. This allowed a change of air which was quickly used up by the two assistants working there, rendering another stoppage necessary. Here was a waste of time from a business point of view, besides incalculable damage to the health of the unfortunate inmates. It is not always realised that a gas or oil flame, which does much to vitiate the atmosphere of the dark-room, may, with a little ingenuity, be used to create a current for ventilating purposes. Even the electric bulb is of some value in this way, and the small half watts with their much greater heating power should be quite effective. Dampness in the dark-room is another fruitful source of ill-health, and we fear that this condition is often concurrent with bad ventilation, making a truly fatal combination. At least one instance of a robust man contracting tuberculosis through working in such a room has recently come under our notice.

We emphasise the necessity for a sanitary dark-room on account of the much greater proportion of time which is now spent in it. When daylight printing was used for the bulk of the work, perhaps two hours a day was the limit of time for which the operator was actually boxed up; but with bromide paper as the only medium, he is shut up practically the whole day. Although we have inferred that a printing-out process is more healthy for the worker than bromide in a badly ventilated room, it is quite possible to conduct it under adverse conditions, the use of the open arc for printing necessitating much more space and

better ventilation than is generally provided. We have in our mind one work-room where three huge pairs of carbons were being used for printing platinotypes giving off unsupportable fumes, while a large dry-mounting press still further poisoned the air. The girl employees looked like candidates for the hospital, and we were not surprised to learn that changes in the staff were frequent.

The war has taught us many things, especially with regard to labour, and nothing has been more clearly demonstrated than that true economy of labour consists in keeping the worker fit by providing healthy workrooms, working a moderate number of hours, and promoting cheerfulness generally. One bad practice which is common in most small businesses is for the workers to remain

indoors during meal times. This should be discouraged, and except in bad weather a little outdoor exercise should be taken. If there is a lassitude and disinclination to do this it may generally be assumed that there is something which requires attention in the state of the premises.

The more sedentary the occupation the greater the necessity for outdoor recreation and exercise. "Health systems" are too dull for most people and are not likely to be persevered in, but walking, cycling, rowing, swimming, tennis, net-ball, and even football and hockey are all valuable medicines, not unpleasant to take, and the employer will do well for himself as well as for his staff if he practises one or other if possible, and encourages his staff to engage in such recreation.

THE BRITISH ACHIEVEMENT IN AEROPLANE CAMERAS.

THE progress made during the war in the design and manufacture of cameras for photographing from aeroplanes has hitherto remained undisclosed except by the few and somewhat sensational brief statements which were published now and again in the lay Press, and which, it may be said, were usually wide of the mark. Messrs. Brock and Holst, in the paper which we reprinted in our issue of February 21 last, made certain sweeping claims to priority which in the following issue provoked denial on the part of two correspondents, both exceptionally well-informed as to what has actually been done in the production of cameras for the British air forces. Since the appearance of that paper we have had an opportunity of inspecting at the Kidbrooke camp of the Royal Air Force cameras representing the whole range of instruments which have been used during the war from the earliest days until its termination. The paper by Major Charles W. Gamble at the Optical Society on March 13 last has also set forth in very great detail the steps by which aeroplane photography has been raised to a great state of perfection. It is therefore well that some account be given of what has been accomplished and of the stages through which the aerial camera has passed.

At the outbreak of war photographs from aeroplanes or airships had been taken only in quite a casual and amateur way, and the military authorities were slow to recognise the great service which aerial photographs would render to the Intelligence Branch of the Army. Within a few months, however, the value of the aerial photographs received recognition, and cameras specially made for the purpose were first used early in 1915. The first or A model, long since abandoned, was of a quite primitive type, consisting of a wooden square-section cone-shaped body, carrying a lens of eight or ten inches focal length and fitted with a Mackenzie-Wishart adapter for envelopes taking 5 x 4 plates. The camera had to be held in the hand and pointed vertically or obliquely downwards by the observer as he stood up in the aeroplane. The Mackenzie-Wishart system allowed of a considerable supply of plates being taken up, but the relative fragility of the envelopes in the circumstances of their being handled by a wearer of thick gloves, coupled with a want of sufficient precision in bringing the plate accurately into the focal plane of an $f/4.5$ lens, caused this form of plate-holder to be abandoned.

Early in 1916 a modified pattern, the C model, of the first instrument was put in the hands of airmen. It differed chiefly from the previous model in the means adopted for holding and changing the plates. The camera was fitted with two magazines, one containing eighteen 5 x 4 plates, in metal sheaths, which was placed immediately over the focal plane, and the other (empty) magazine below it and to one side, the camera,

of course, pointing downwards. By means of a horizontally moving metal plate, the lowermost of the plates awaiting exposure was pushed to one side and was received in the lower magazine, the operation of thus changing the plate also resetting the focal-plane shutter under cover of the moving metal plate. The principle of mechanically changing plates by discharging from a holder placed mouth downwards into one placed mouth upwards has been retained in later models in which the changing mechanism itself has been further improved.

The two foregoing cameras were both of wood, the disadvantage of which, as pointed out by Major Gamble in his paper, was the liability to expand or contract under the very wide range of temperature and climatic conditions to which the cameras are exposed. Inasmuch as a very slight alteration of the distance between an $f/4.5$ lens and the sensitive surface may disturb the definition, recourse was had to cameras of all-metal construction or to one consisting of wood framework, constructed so as to obviate expansion and covered with metal mounted thereon so as to cause no stresses in the structure in the event of its expansion. The E camera of the R.F.C. introduced in 1917 was an all-metal camera of this type, and was fitted with a changing mechanism similar to that of the C model, but with the difference that the plate was changed by pulling a cord, and, the occulting metal plate being thus dispensed with, the camera included a capping shutter to cover the aperture in the focal-plane blind during re-setting. A further new device first introduced in this model was an adjustable lens cone by which lenses of from 8 to 10½ inches focal length could be fitted and readily brought into use.

Up to this point all the cameras employing plates were operated, as regards changing the plate, entirely by hand, a system which had considerable disadvantages. Simple as an ordinary photographer would regard the operation of the changing mechanism, the fact that it had to be placed in the hands of men entirely unfamiliar with photographic apparatus called for a changing device which would be free from mishandling by the human operator. It need hardly be said that the airman has many other things to do besides taking photographs, and that he carries on his work always under the conditions of fire from enemy anti-aircraft batteries and of attack from enemy machines. Thus the next step, and one which brought the aeroplane plate camera almost to its most perfected form, was to provide a mechanical means of changing, operated by power other than that of the airman and brought automatically into operation immediately after an exposure had been made. This was done in the L camera first used by the R.F.C. early in 1917. With it the operator

had simply to use a Bowden release in order to make an exposure: the rest—resetting the shutter and changing the plate—was done mechanically and automatically. The ingenious device introduced for this purpose consisted of a small propeller mounted on the aeroplane and connected to the camera by a flexible shaft. This provided sufficient power for the operation of the plate-changing mechanism, the changing gear coming into operation on the observer releasing the Bowden lever.

An improved model of this camera came into use in 1918 as the LB and has proved the most successful of aerial instruments. It differs from the type just mentioned in being fitted with a self-capping focal-plane shutter which can be entirely removed and replaced by another in case of derangement. Moreover it can be adjusted as regards slit-width by an external lever, and there is the further provision of operating the plate-changing by hand or power as necessary and of instantaneously altering it for use by one or the other means. A further improvement was the series of most rigidly made and finished lens cones, enabling lenses of 4, 6, 8, 10, and 20 inches focal length being used on the one camera.

The principle of a propeller drive for the mechanical changing of plates was also applied to a camera of much larger size, for 18 x 24 cm. plates, first used by the R.A.F. in 1918. The camera, which perhaps may be said not to have been quite fully perfected at the time of the Armistice, is fitted with lens cones allowing the use of objectives of from 7 to 20 inches focal length.

Other cameras of simpler type have been used both in the

Royal Flying Corps and the Royal Naval Air Service for purposes more or less special to the requirements of these services. Certain of these are cameras fitted with a stout handle or grip by which the instrument can be held and pointed obliquely in order to produce a type of photograph distinct from that obtained with a vertical direction of the lens axis. Thus in preparing for operations with tanks in France, photographs taken obliquely are necessary in order to yield an idea of the nature of the ground over which the attack is to be delivered; and similar oblique pictures are taken for many purposes of the Admiralty, for example, in order to obtain records of the correctness with which the masters of ships proceeding as a convoy are carrying out their instructions as to formation.

But perhaps the camera evolved for aeroplane work which would provoke the greatest admiration of a connoisseur in mechanical devices is that known as the F, and first used by the Royal Flying Corps in 1916, after having passed through its trials at Farnborough during 1915. This is a camera taking a continuous series of 5 x 4 pictures on a roll of film sufficient for 120 exposures. The mechanism is operated by a propeller so that as the aeroplane travels the photographs are automatically taken at intervals corresponding with a certain number of revolutions of the propeller. Simultaneously with the exposure of each section of film a tiny record is made on each (by means of a small supplementary lens) of the reading of the height of the machine and of its compass bearings so that each negative is provided with a record of the direction of flight over the territory which is being photographed.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
The Camera and the Lens (Jan. 10).
Managing the Sitter (Jan. 24).
Backgrounds (Jan. 24).
Studio Exposures (Jan. 31).
Artificial Lighting (Feb. 7).

Printing Processes for Portraiture (Feb. 14).
Studio Accessories and Furniture (Feb. 21).
The Surroundings of the Studio (Feb. 28).
Studio Heating and Ventilation (March 7).
The Postcard Studio (March 14).

THE PRINTING-ROOM.

No matter how small a business may be the arrangements for printing should receive the most careful attention, and make-shifts only employed when absolutely unavoidable. In a one-man concern every device which will save time should be adopted, as the photographer's time is naturally of more value than that of a junior assistant. Moreover, proper rest is necessary to efficient working, so that even if an energetic man is willing to put in a sixteen-hour day he should refrain from doing so unless he wishes to bring on a premature collapse. I mention this because I recall the case of an unhappy man who opened his studio at 10.30 a.m., interviewed sitters and made negatives till 9 p.m. and did his printing and mounting outside those hours, his arrangement being so primitive that while negative work was in hand nothing else could be done.

If it be possible, a separate room, or at least a portion of the dark room, if large enough, should be fitted up for printing exclusively, so that it can be carried on without interfering with other operations.

Adequate sink space is the key to easy work. I am rather a crank on this subject and would almost go as far as to put in sinks wherever there was room. As I have said many times

it is easy to turn a sink into a bench by covering it over when not needed, and while the plumber is at work the extra cost is not great. Most dark rooms are inadequately supplied with washing accommodation, and this is one of the greatest errors which can be made. Lead-lined sinks are generally recommended and for negative work leave nothing to be desired, but for printing I favour stoneware sinks, which can be used as washers for small and large sizes alike. Where large quantities are handled they are excellent for development as they save the cost of large dishes and avoid the risk of breakages.

As bromide and gaslight papers are used for the greater part of the prints now issued I will give details of a printing-room which I fitted up and from which large quantities of prints are being turned out. The room is about fifteen feet square and is fitted with benches along two sides and a row of Doulton stoneware sinks along a third. The entrance is on the fourth side, and this is so trapped that free entrance and exit can be obtained while work is in progress. On one bench are placed the negatives to be printed with the order forms, while below are drawers for storing sensitive papers. On the next bench are the printing-boxes, three being

strip printers capable of taking any size up to half-plate, while two others accommodate negatives up to whole-plate and 20 x 16 respectively. Trays for unexposed and exposed paper are placed between the machines, and those containing the prints can be carried to the developing trays without unnecessary handling. Four large stoneware sinks are ranged close together for developing, fixing, and washing. In the first stands a porcelain dish containing amidol or M.-Q. developer; the second is filled with acid hypo, while the third and fourth serve for washing, water running into them the whole time. The prints are transferred from the hypo to the first sink, and after about ten minutes to the second, where the washing is completed. With this arrangement several thousands of prints in assorted sizes are easily made daily. This scheme may be carried out on any desired scale, a single printing-box and a couple of sinks being sufficient in the majority of cases. The point to be aimed at is the arrangement of apparatus so that it is always ready for use.

There are many good printing-boxes on the market, and it is better and probably cheaper to purchase one of these than to make one, although this can easily be done by anybody with a knack for carpentry. These should have a ground-glass diffuser and a vignetting arrangement. For this latter I prefer a sheet of clear glass on which vignette forms can be laid; it is then easy to modify the shape of an opening by putting another on top, or at one side, or by adding a torn piece of card. Vignettors and loose pieces can be kept in position by laying small weights upon them. For general use the printing-box should take negatives up to whole-plate, as a larger size means unnecessary labour in handling. If many large negatives have to be printed a 12 x 10 box and a strip-printing box to take up to half-plate will be found convenient. The illuminant will usually be electric glow lamps, from one to half-a-dozen being required according to the rapidity of the paper used. With such papers as Velox, Kodura, and Cyko, a short exposure to a strong light will give better results than longer exposure to a weak one, especially when vigorous negatives are being printed.

Where no current is available incandescent gas will be found a good substitute, but, of course, in this case the burner must be at the side of the box and the light received upon a silvered or enamelled mirror at the usual angle of forty-five degrees. Failing gas a good duplex or circular wick lamp may be used, care being taken to keep the burner very clean and to use only good quality kerosine oil. Acetylene is an excellent printing light, but should only be used in a very large and well-ventilated room. Used in close quarters it causes headache and nausea in many people. Whatever form of printing box be used it is desirable that the negative should be illuminated by red or yellow light, between the exposures, as this greatly facilitates the placing of the paper upon the negative. With electric light this is usually done by fitting a two-way switch and placing an extra, red and yellow, bulb beside the white ones inside the box. With gas or oil a yellow glass exposing shutter must be fitted, and this may conveniently be operated by a treadle. Boxes fitted with a single bulb only may be improved by fitting four pieces of ordinary looking-glass so as to make an inverted hollow pyramid; when correctly adjusted there should appear to be five lamps when the interior is viewed through the negative opening. When working with thin negatives it is easy to reduce the light to any extent by interposing thicknesses of white paper, the best position for this being on the surface of the ground glass diffuser. It is very desirable that the top of the printing box should be so fitted that a large sheet of paper can be used if needed, not only for white margin work but for multiple exposures upon one sheet. A very handy way of working is to make six cabinet exposures upon a 15 x 12 sheet. This is done by exposing three along one edge and then turning the

sheet and exposing along the other edge. Not only does this tend to uniformity of colour and depth but it saves time in handling and automatically sorts out the orders.

Some system of exposure test should always be available so as to ensure the best results from a difficult negative or when taking up a new brand of paper. Obviously the ordinary strip method cannot be applied to most printing boxes, but it is quite easy to make an actinometer plate by exposing an ordinary negative plate in strips to a weak light and developing fully out. This can be placed under the negative and a long exposure given; it is then easy to calculate the exposure required. A useful range is to make the scale so that the thickest end admits one-thirty-second of the light which passes the clear end.

For large work printing frames are necessary unless a printing box of exceptional rigidity of construction is available, and even then my preference is for frames of the box form. Most bromide paper is now on a fairly stout base and much more pressure is necessary for this than for the older printing papers. In exposing large prints it is desirable to work at a considerable distance from the light to secure evenness of illumination; twice the longest side of the plate is a safe distance.

The fixing bath should be of goodly dimensions, with regard to the work to be done, and it should be replenished from time to time with fresh solution. It is a great mistake to allow the bulk of the bath to decrease much, as not only is the solution already weaker, but there is not sufficient for the prints to be moved about freely. Practically no amount of immersion without movement will safely fix a number of prints. I have tested some which have been massed together in the hypo for over an hour and found unaltered emulsion.

The washing after printing is of the greatest importance and does not usually receive the attention it requires. There is no better way for large or small quantities than hand washing from one sink or dish to another. If a range of three sinks with overflow plugs can be arranged the prints can be placed in the first direct from the hypo, the water running the while. When a good number has accumulated they are transferred singly to the second sink and so on to the third. If no assistant be available the printer should stop at, say, each gross of prints to make this change, or he may leave all in the first sink until he has finished his batch. But this plan is not to be recommended, as it leaves too many prints to be handled properly.

Platotype printing is so simple that it requires little special arrangement, the only special appliance needed being a gas ring for heating the bath for sepia work. For exposing, a mercury vapour or arc lamp may be used in poor light; the arc if used direct is rather apt to give flat prints, so that it is preferable to use a pattern such as Marion's Northlight printing lamp, which gives a powerful reflected light. If this lamp be used it should be placed in a fairly large well-ventilated room.

For carbon printing a slightly different arrangement is necessary; the work-room should be fitted with a large deep sink with boards to confine the unavoidable splashing. The developing tank should be warmed by a gas ring below, or, failing this, have a constant stream of warm water running into it. I have found nothing better for this than one of Fletcher's open pattern heaters as fitted over inventory basins. These supply an ample supply of hot water, and as the heat can be regulated they can be used by the addition of a smaller rubber tube as a "squirt" for local development. I have found plate glass the best covering for the mounting bench. Ample space should be allowed for carbon work so that no splashes from the alum bath are likely to reach the mounting board or developing tank.

THE PHOTOGRAPHERS' ASSISTANT.

THE masters plead inefficiency as excuse for low wages, and bewail the lack of good assistants.

The assistant pleads lack of means and absence of encouragement as an excuse for inefficiency. Which is right?

The position of the average assistant in the average photographic business has been in the past anything but an enviable one from any point of view. He is expected to handle successfully a large range of materials which are sensitive to many influences, often in circumstances and with apparatus that are in themselves handicaps to the production of good work. The knowledge and skill required to cope with the never ceasing stream of technical problems are perhaps greater than in any other craft, not only because of the existence of those problems, but also because the photographic business is not so sharply sub-divided into its many branches, and an assistant may be called upon at any time to do work of a kind quite outside his ordinary job, and is expected to produce results equal to those of a man whose regular practice it is.

That roughly suggests what is expected of the assistant as regards his work. Usually he is required also to keep an appearance above that of a wage-earner, such as a mill-hand, letterpress printer, or bricklayer, and to cultivate the affability of speech and manner which is perhaps the principal asset of the successful doctor or lawyer. The dark-rooms in which many assistants spend nearly a third of their lives and most of the hours of daylight often are little better as regards health or comfort than the workrooms of many years ago described so vividly by Charles Kingsley in "Alton Locke."

So that compared with other crafts, quite apart from the rate of wage, photography exacts more, and offers less. That the average rate of pay, and consequently the social position, of the photographer's assistant, is comparatively very low is a fact, obvious and admitted. What are the natural consequences of this?

I think that assistants may be divided broadly into two classes. The first class has caught the fascination which undoubtedly exists in photography for anyone with average intelligence and a little imagination. If to these qualities the assistant adds ambition he usually becomes the master-man eventually, but the business knowledge essential to success is not easily gained during the assistant period. The second class, by far the larger one, and probably still more increased by war recruits to the business, comprises those who are by nature slack, unintelligent, or unambitious, and those for whom the handicaps and discouragements incidental to the struggle for success in such an exacting calling have proved too great.

The worker who has struggled to efficiency in spite of the many difficulties in his path still finds that adequate reward is not easy to get. He may have worked for a low wage for the chance of getting special experience, but the last rate of pay earned is still too often taken as the measure of a man's value. Many employers, far too many, are imbued with the idea that if they only advertise and sack, advertise and sack, often enough they will eventually secure for the inefficient's wage either one of the skilled men willing to work for little money to increase his experience, or one of the disappointed ones for still less. The result is that the latter either recover a bit of their ambition or sink entirely to the level

of the man who only does just enough, and that hardly well enough, to earn his salt. The ambitious man very quickly picks up what he wants to learn and moves on, so that this type of employer is seldom suited for long. Another type of employer has greatly increased of late years in the shape of the "company shops," who turn out large quantities of inferior work by semi-skilled workpeople on the "factory" principle. The wages offered by these firms to inefficient are often much higher than those paid by firms of standing to expert assistants.

I have tried to show that the conditions fostered by employers tend to discourage a man from becoming efficient, besides offering him little reward if he overcomes the difficulties, often needless and stupid, placed in the way of his improving his ability. That there is "plenty of room at the top" is not true of photography, for there are always vacancies for those willing to accept a low wage; but a man who has made a study of his business and knows his real ability is often turned down in favour of one who will work for a little less money. It does not seem to occur to the average employer that the careful and conscientious worker can easily save the extra pay he asks, both in time and material as well as in quality of output. Yet we find the employers continually bewailing the difficulty of finding efficient assistants!

Make the life of a really good assistant worth living, by giving him tools and material that will be a pleasure to work with, in clean and healthy workrooms, and pay him a wage that will permit him to have a decent home that he can take a pride in, as well as to have a hobby or two and the time to enjoy them in, and there will very soon be an army of assistants making themselves efficient. A few employers have realised this, and find it pays them well to pay their staff well.

Among those about to return from the Army employers will be looking for experienced assistants. Let me tell employers of a spirit that they may expect to find in these men, which I have noticed spreading among all ranks during the past year or more. It is a spirit of antagonism to injustice, and is perhaps a sort of reaction against the harsh "militarism" and so-called "discipline" of the Army. It is not rebellious or antagonistic to authority, but men have been taken out of their ruts, and have been living a life summarised by "look after yourself, for no one else will." Living huffer-mugger with men of all classes, Jack finds out that he's as good as his master, and often better. This has resulted in a spirit of camaraderie flavoured with independence, which shows itself outwardly among the men by willing work so long as those in authority do not "come it," and by obvious resentment and often by obstructionist methods if they do. Per contra, officers and N.C.O.s find it pay better to recognise this new spirit, which has replaced the old "shirk while he isn't looking" idea, and there is increased mutual confidence and respect. Men are told, as recruits, that the Army can tame even lions, but it has gone further, and is taming even sergeant-majors.

This new feeling of self-reliance and impatience with injustice, if it can show itself so strongly in the most autocratic institution we have, is not likely to be shed when the khaki is left behind.

D. CHARLES.

THE SHOPS ACT.—A reply to a correspondent last week has, it appears, given rise to a wrong impression in the minds of several readers. Our correspondent made certain inquiries to which we replied specifically, but it must not therefore be assumed that there has so far been any relaxation of the Early Closing Order, according to which the great majority of retail businesses compulsorily close at 8 o'clock.

THE CITY SALE AND EXCHANGE informs us that its four chief branches, namely, those in Aldersgate Street, Lime Street, Fleet Street, and King's Road, Chelsea, each publishes a list of second-hand apparatus, each representing a different stock of goods. The list sent to us with this intimation—that from the Aldersgate branch—specifies a very great variety of lenses and of cameras of all descriptions.

HOUGHTONS' SHOW AT LEEDS.—Messrs. Houghtons, Ltd., are arranging an exhibition of apparatus and other specialities of theirs for the professional photographer at the Grand Central Hotel, Brig-gate, Leeds, from March 24 to 29, both dates inclusive. The exhibition will be attended by Mr. Ibbs, manager of the firm's professional department in London, and Mr. Richards, the Northern representative. Among apparatus which will be shown is the Ensign de luxe printing cabinet (a notice of which is held over), the Pawl bromide strip-printing machine, and the Ensign rotary bevelling machine. Other exhibits include the Ensign dry-mounting tissue, postcards, papers, etc., of which samples will be obtainable on presentation of trade card. There is no doubt that photographers in the North will take this opportunity of seeing the many well-designed and manufactured specialities for their use, for which Messrs. Houghtons have long enjoyed a high reputation.

THE AIR RAIDS ON LONDON.

DAMAGE DONE TO PHOTOGRAPHIC AND ALLIED PREMISES.

DURING the period of the war the Censorship has been so strict that no details could possibly be published as to where the bombs had dropped, and what damage had been done to the trade, in the twenty-five air raids, Zeppelin and aeroplane, which took place over London from May 31, 1915, to Whit Sunday, May 19, 1918. The veil of secrecy has now been lifted, and it is permitted to publish the official details which have been issued by Lieut.-Commander Sladen, R.N., who was then the chief of the London Fire Brigade, but has now retired on a pension of £720 a year; and these that follow have to do with damage done to photographic and allied premises. The first damage to trade premises was in raid No. 1, which took place on Wednesday, September 8, at 10.45 p.m., when 336 sets of premises were damaged; 23 incendiary and 21 explosive bombs were dropped, 5 people were killed, and 33 injured. By an explosive bomb which dropped, Messrs. W. Hayward and Sons, Ltd., of 65, Farringdon Road, E.C., photograph frame-makers, had their building and the contents damaged by breakage. In raid No. 4, which occurred on Wednesday, October 13, 1915, at 9.27 p.m., the premises of "The British Journal of Photography" suffered as the result of an explosive bomb, the building and the contents being damaged by explosion and dirt. Close by a bomb fell, which damaged the Lyceum Theatre, killed 19 males and females, injured 12 seriously, and slightly injured 9 others. As the result of an explosive bomb which fell at 100, Finsbury Pavement, E.C., the London Portrait Company, Ltd., had their building and contents damaged by explosion. In raid No. 9, which occurred at 11.36 a.m. on June 13, 1917, damage was done at 77-79, East Road, Shoreditch, to the premises of the London Manufacturing Company, photo frame-makers, the window glass being damaged by breakage. Messrs. G. Johnson Brothers, of 43, Beech Street, City, metal photo frame-makers, also had their window glass damaged by an explosive bomb. In raid No. 10, which occurred at 10.36 a.m. on Saturday, July 7, 1917, when between twenty and thirty huge Gothas flew over the City and Central London in broad daylight and leisurely dropped sixty-six bombs in the busiest districts, of which, fortunately, seven failed to explode, enormous damage was caused to City warehouses, particularly in St. Bartholomew Close, Little Britain, St. Martin's-le-Grand (where the General Post Office was badly damaged and the military sentry killed), Aldersgate Street, Golden Lane (Finsbury), Bread Street (Chipside), St. Pancras, Stoke Newington, Shoreditch, Bermondsey, Holloway, Peckham, Limehouse, Holborn, Old Street (City), Haggerston, Bow, Southwark, and Hoxton. In all, 903 sets of premises were affected, 41 persons were killed, and 87 injured. In this raid there was damage caused to a big block of buildings in Chiswell Street by an explosive bomb. Mr. C. A. Rudowsky, of 89, Chiswell Street, E.C., had his premises severely damaged by explosion, and himself had an almost miraculous escape, and the City Frame Company, Ltd., of 34, Coleman Street, E.C., photo frame manufacturers, had their window glass damaged by breakage. In raid No. 11, which occurred at 11.50 p.m. on Tuesday, September 5, 1917, Mr. L. Bure, of 14, Castle Street East, W., photograph frame importer, had his window glass damaged by breakage. By an explosive bomb which fell in John Street, Adelphi, W.C., the Camera Club, at 17, John Street, had their premises damaged, the chimney-stack, roof, and window glass being damaged by breakage. Messrs. F. W. Woolworth and Co., Ltd., of 178-80, Edgware Road, W.2, photo frame dealers, also suffered as the result of an explosive bomb, the window glass being damaged by breakage. In raid No. 12, which occurred on Monday, September 24, 1917, at 8.8 p.m., Messrs. W. O. Parker and Co., of 100, Russell Square Mansions, suffered as the result of an explosive bomb, the window glass being damaged by explosion. The effects of this bomb were most disastrous, as in these mansions ten males and one female were killed, fourteen males and ten females injured, and two males afterwards died. The Award Film Service, of 5, Edward Street, Soho, W., suffered, also as the result of an explosive bomb, a building of four floors, about 50 ft. by 20 ft., being damaged by the explosion and breakage, and the window glass by breakage. Messrs. F. R. Batt and Co., Ltd., 10-11, Wardour Mews, Soho, W., had their window glass damaged by breakage. They are X-ray apparatus makers. In raid No. 13, which

occurred at 7.58 p.m. on Tuesday, September 25, 1917, Messrs. Haigh and Co., of 240, Old Kent Road, S.E., photo frame manufacturers, had the window glass damaged by breakage, as did Mr. C. E. Boxall, photographer, of 246, Old Kent Road, S.E., both as the result of the same explosive bomb. No further damage was done in any raid to trade premises until the last of the series, which occurred on Whit Sunday, May 19, 1918, when no fewer than 300 sets of premises were affected by the twenty-nine explosive bombs which the Huns dropped, killing 34 people and injuring 94 others. By an explosive bomb which dropped in Bolsover Street, Upper Marylebone Street, W.C., wrecking St. Clements' House, Ltd., which was used as a ladies' club, the window glass was wrecked of 196, Bolsover Street, tenanted by Messrs. Watson and Son, X-ray apparatus manufacturers. This was the only damage caused, and concluded the Hun method of warfare on defenceless women, children, and men by means of bombs from Zeppelins and aeroplanes, much to everybody's relief.

AN OUTSIDE VIEW OF THE SOLICITATION SYSTEM.

[PORTRAIT photographers who live by the invitation system will no doubt thank us for reproducing part of an article in the current issue of "The Advertiser's Weekly," entitled "The Lines that Hook the Oriole." It will here be seen with what pertinacity those who offer to take portraits for nothing bombard possible members of the public with letters, statements in some of which must surely impress the recipient as having a very slender relation to facts. When it is possible for a professional writer on advertising to collect such specimens as these, it is time for photographers to cease shouting from the housetops that they are professional men. Not even the grocer and the fishmonger are such servile beggars for custom.—Eps. "B.J."]

For keen competition in business commend me to the fashionable photographers. Their methods of securing sitters are most persuasive, and must account to a large extent for the generous supply of pictures of society beauties and others appearing in the illustrated weeklies and the daily newspapers.

It would take pages of "The Advertiser's Weekly" fully to criticise the methods of the dozen or so high-class photographers who wrote in for "the honour of a sitting." I will take a few whose letters vary in style. A certain well-known Bond Street firm sent a nicely expressed, well-typed letter with the personal touch, saying, "We should be extremely obliged if you could give us a complimentary sitting. . . . We are desirous of taking this for publication in the illustrated society and weekly papers, and shall be glad if you will accept a set of portraits passed by you for publication. If the sitting, which we hope you will be good enough to grant us, can be exclusive to ourselves for this particular purpose, we shall be pleased to present you with one of our pencil sketches. . . . in addition to the copies. . . . We have been asked by the editors of several papers to let them have these photographs as soon as possible." It is a nice bait, but I am inclined to add the word "query" after the last sentence. In striking contrast, the next application, from a "Court photographer," came a Roneo letter with date, the name of the recipient, and the event filled in in handwriting. The opening ran: "The Press are desirous of securing copies of your portrait for publication in the leading illustrated periodicals. . . . there will be no charge made whatsoever, and you will be under no obligation to purchase"—but no offer of a free photo. Another unambitious effort by a Royal warrant-holder was a letter similar to the former, which began: "I have been asked by the press (small p) to secure copies of your portrait for publication in the leading illustrated papers. . . . The expenses of the sitting are entirely my own, and you would be under no obligation whatever."

A really appealing letter, typed neatly on good stationery, likely to make a good impression, reads:—

"We shall greatly esteem the honour if you will permit us the favour of a special sitting for the purpose of making an up-to-date camera study for the illustrated papers. . . . Finished proofs will be sent to you, and we shall esteem it a courtesy for you to retain two of these finished photographs as a souvenir of your visit, free of charge. We enclose an appointment card; on receipt of same from you a studio and dressing-room will be reserved."

An excellent specimen of effective letter-writing.

Several other firms wrote asking to be "favoured" or "honoured" or would the recipient "be good enough," etc., as "the best society journals are asking for your portrait." As an inducement, one well-known studio made the indefinite offer: "We shall also have much pleasure in asking your acceptance of approved positions finished in a permanent process"; another was kindly disposed to give "a complimentary copy," and a third "a finished copy of the two proofs you like best."

The gum of the budget of letters received came from a photographer whose work figured daily in the public prints, and who shows by his correspondence a keen knowledge of human nature and how "to hook the fish." His stationery is in the best of good taste, his letters are neatly typewritten, and his follow-up system effective, combining an excellent canvas by correspondence. As a contrast to others in the business, a few extracts will prove the pulling power of this fashionable letter-writer, who wrote:—

"May I bring before your notice that I have my own private Press agency in the City for the circulation of photographs and information to the papers both at home and abroad, and I am in an exceptional position for supplying society papers with portraits of ladies or gentlemen. . . . If it meets with your approval, I should be most happy to take your portrait in order that I may have a picture to use for the above purpose; and as I should very much like you to have some finished copies to show your relatives and friends, I will send for your acceptance, free of any charge or obligation, one finished picture from any three proofs you select."

Getting no reply within a few days, this energetic gentleman followed up with a letter marked "Urgent," in which he says:—

"I beg to remind you that some of the society papers are calling upon my Press agency for a portrait of you. I should therefore be very grateful if you can now see your way to acceding to my several invitations."

He had only given one. The letter finished with the old tag in new wording about the presentation picture. Failing to draw the sitter, another follow-up was received, which ought to induce any bride-to-be to patronise a gentleman so interested in her affairs. As a model of excellence in follow-up correspondence, I reproduce it in full:—

"In writing to you again, I beg to say that I have no desire to importune you, but am only afraid my previous letters have either gone astray or have been overlooked by you owing to pressure of circumstances. As I am aware that you must be very busy and may not have time for a sitting, would it be pleasing to you to loan me a good photograph (one which was taken to your own order and not in answer to an invitation from any photographer)? This I would duplicate and circulate through my private Press agency without any charge or worry to you in any way whatever. Needless to say, if you have time I would prefer a sitting, though in either case would you let me have a few lines of information suitable for reproduction with the picture?"

The illustrations given of how to and how not to conduct advertising by post show that there are to-day many firms of good standing who have yet a great deal to learn in the art of letter-writing.

FORTHCOMING EXHIBITIONS.

April 17 to May 22.—Hammersmith Hampshire House Photographic Society Annual Exhibition. Two open classes. Joint secretaries, J. G. Abrahams, 41, Hamilton Terrace, London, N.W.8; A. H. Page, 12, Lime Grove, London, W.12.

EXPORT FREE LIST.—It is announced by the Board of Trade that from March 15 last a large number of goods have been removed from the list of articles exportable only under licence or guarantee, and may now be freely exported to all non-enemy destinations and to those enemy destinations with which trading is now permitted. Among these goods are:—

- Photographic goods, but not chemicals therefor
- Sensitised paper and plates.
- Cinematograph films, raw or printed.

In reference to the prohibition of chemicals for photographic goods, it requires to be noted that metal is included among the "drugs" which may be exported.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Specialization and Efficiency.

THE advice to specialise in one or perhaps two particular branches of work is frequently given to the photographer whether he be a master, assistant, or amateur. This advice is often rather vague, first as to the "why" and more so as to the "how" of the question.

I am writing more particularly for the benefit of the assistant, because one who has a business of his own has usually found out what particular lines pay him best, and how to push the sale of them. Still, it is strange to notice the great number of photographers' note headings stating this, that, or the other to be a speciality (or "speciality," or "specialité"), but which can form only a very tiny portion of the business done. For instance, an order comes to quite a small studio for an oil-painting. The photographer puts the work out, takes the profit, and feels pleased with himself at having launched out into a high-class and profitable branch, so has all his stationery imprinted for ever after "Oil-paintings a speciality," in the probably vain hope of a succession of such orders. Another advertises "Wedding-groups" or "Child-portraits" as his speciality, not necessarily because weddings are frequent in the one man's neighbourhood, or that the second is extraordinarily successful with children. If any definite reason for printing these phrases on note-paper can be given, it usually is only that "it sounds well."

Another sort of specialisation was criticised in a letter recently by an "All-round Hand" on behalf of his class. He described a retoucher whose work was so "effective" that the portrait looked very nice but not a bit like the subject, and a receptionist whose "specialising" in her own department was so water-tight that she failed to recognise what was wrong with the portrait when complained of.

I do not call these things specialisation at all. I don't know what to call them. We have specialists in the Army. In the infantry a soldier may be, for example, a Lewis-gunner, a sniper, or a mess-waiter, but he must be a good infantryman first. I think the same applies to a craftsman, such as a journeyman photographer.

When an assistant has had a few years' practice and can, say, correctly expose on a well-arranged group, develop plates evenly, make good bromide prints that will tone well, and make a fair show at one or two other departments he will realise that some jobs are better paid than others. That will be the first reason "why" he should specialise. Then he will find that one branch of work appeals more than others, not necessarily because it seems more lucrative or easier, nor because it is a clean-hand job, but because it is more interesting. In short, he likes that particular work. If he does not like one branch better than another the assistant should go further afield for wider experience till he does find work he can like. One spends nearly all one's life in work, so why not expend a little effort in finding something to do that one can enjoy doing? That is the second "why" for specialisation. After a bit one finds that one is able to do certain work better, and with less effort, than other kinds. Again, this is not necessarily because it is easy work, but one "picks it up" more easily, and one feels more sure of one's self in doing it. In ninety-nine cases out of a hundred the kind of work that a man finds he can do best is the same as the kind that he likes best. It's quite natural when you come to think about it, and it works both ways. Anyone likes doing what he can do well, and in doing it with interest is likely in time to do it as well as it can be done. When that stage is reached, surely he is in a position to demand a higher price for his work.

That is the right sort of specialisation. It does not prevent a man being skilful in other branches. Rarely is it possible for a worker to reach the highest grade of ability in any branch of photography without at least a working knowledge of other branches. Retouching is probably the line in which the worker usually knows least of other departments. The aim of so many retouchers is to produce a beautifully modelled "effect," and to make a face resemble one of those nicely rounded plaster casts that they practised

light and shade from an art school. They like to call forth the remark "How nicely retouched," forgetting that the greatest art is to conceal art, and that the best retouching is recognised by its apparent absence. A retoucher should know how his (or more often her) work will print, not only in a P.O.P. proof, but in other processes and surfaces, and be able to modify it accordingly. No one can be considered efficient unless the effect of his work on subsequent stages is understood and intelligently handled.

And that brings me to the question of efficiency. When an assistant decides to specialise, obviously he must reach a certain stage of efficiency before he can claim to be a specialist. There is an absolute test by which he can know when he has reached that stage. His employer or manager will be in the habit of giving the assistant instructions as to what is required, and how to set about it. The assistant should aim to be able, in at least one branch of work, to look his chief in the eye and say "Leave that to me." That is the test of efficiency.

Now for how to set about it. Assistants in photography are at a very great disadvantage, usually as regards so-called experiments and other essentials to improving their work. I have never yet met an employer who offered an assistant the use of his studio on an "off" afternoon to try his hand at posing and lighting, nor one whom one felt like asking for that favour, still less one who would supply a few plates and some developer for practical tests. Therefore, unless one assists in the studio itself it is not easy to get even a starting knowledge of this work except in at home portraiture. All the same, within limits this is a very good school, for when the student can make a good portrait in an ordinary room or garden he won't have much difficulty in doing better studio work. A pair of "smoked" spectacles are useful to see the light and shade effect by eliminating much of the colour in the subject, and much practice may be got without using plates.

Of course, books are necessary. A pile of old "B.J.'s" and Almanacs provides a host of useful knowledge. The great thing, though, is to learn to work systematically and to cultivate the power of observation, for in photography it is often apparently small things that make big differences. A splendid idea of what I mean by system can be got from the "Watkin's Manual," which will soon teach the student what he wants to know about exposure and development.

In printing it is a good idea to take one good negative, one flat one, and another on the contrary side, and practice on these only till one can produce the best possible prints with ease and certainty. With a standard developer, at normal temperature, try various lengths of exposure and varying length of development. When the different sort of results obtained have been carefully observed, the next thing is to start over again with a weaker light, or at a greater distance from the light, which amounts to the same thing, and compare the results with the first lot, noting where improvement has been effected and where not. I am referring to bromide printing. It is not necessary to spend a lot, even at war prices. Half-plate paper cut into four is quite large enough for practice work, but the great thing is to take time to observe closely the differences between different prints, and to aid this it is essential to mark on the back of each strip the exposure and length of development, and other variable factors.

It is only by starting slowly and systematically on the lines suggested that a really good "grounding" can be obtained in any subject, and it is only with good grounding that one can rapidly become efficient when the elementary stage has been passed. Attempts to short-circuit the process by practising only on the more advanced stages leads to mediocrity. It is that half-baked sort of ability that has brought the term "all-round hand" into such disrepute. Every assistant should be an all-round hand, with one or two special abilities. A man of that kind is ready to tackle any sort of job that comes along, whether it comes within his previous experience or not.

Assistants who reach that stage of ability have nothing to fear from the snap-shooter who thinks how nice it must be to be working continually at such an interesting hobby, and whose enthusiasm gives him or her enough ability to get a start (and a disillusionment) at a few shillings a week. It is enthusiasm that is needed to get on, and no one can enthuse over poor work. Any assistant who feels that the class of work he is employed in is not worth doing

well is hereby advised to do it as well as he can all the same, whether the pay makes it worth while or not, and whether that particular employer appreciates the effort or not. It is always practice that makes perfect, if the practice has an object and some system behind it; and when such efforts have had the desired effect by improving ability, then is the time to get a better job.—D. CHARLES.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

- Applications, March 5 to 8:—
CAMERAS.—No. 5232. Cameras. E. L. Walker.
HAS-RELIEFS.—No. 5486. Means of obtaining photographic bas-relief and dies. A. J. E. Hill.
PHOTO-COPYING.—No. 5406. Photo-copying machines. W. B. Dawkins.
PROJECTION APPARATUS.—No. 5357. Means for operating, delivering, and displaying optical, etc., projections. J. Davis.
CINEMATOGRAPHY.—Nos. 5350 and 5353. Cinematograph projectors. T. Boyle and W. Whitehead.
CINEMATOGRAPH PROJECTION.—No. 5233. Projecting cinematograph pictures. E. L. Walker.
CINEMATOGRAPHY.—No. 5306. Cinematographs. R. S. McConnell.
CINEMATOGRAPHY.—No. 5823. Cinematograph apparatus. W. T. Adamson.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

METALLIC LANTERN SCREENS.—No. 104,883 (March 17, 1916). The support is coated with a metallising substance in the form of a paste comprised of a suitable metal in the form of powder, to which is added brown varnish, siccatif, and turpentine, the paste thus obtained being applied with a brush and then rolled. As a "matting" coating a solution of white gum and zinc white is used.

An example of the metallising substance is as follows:—

Powdered aluminium or other metal	100 grains.
Brown varnish	200 c.c.s.
Siccatif	300 c.c.s.
Turpentine	300 c.c.s.

The paste obtained is applied with a brush and immediately rolled.

In the "matting" substance the proportion of zinc white varies according to the dulling effect required. As an example, to each litre of water 25 grams of white gum and 5 to 25 grams of zinc white are added.

The solution thus obtained is applied with a brush in one or more coatings: the coatings are transparent, supple, and milky, and the screen can be rolled without inconvenience. Joseph Chanteux, 63, rue Traversière, Brussels, Belgium.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

MONOPHENS.—No. 380,787. Photographic developers (chemical). White Band Manufacturing Co., Ltd., 121, Solihol Road, South Croydon, Surrey; manufacturing chemists. November 27, 1917.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register:—

V. IT. D. PLEX (Design).—No. 380,095. Photographic prints. Vincent, Brooks, Day and Son, Ltd., 48, Parker Street, Kingway, London, W.C.; lithographers.

PARAMIN.—No. 380,068. Chemicals for photographic purposes. Major and Co., Ltd., Wincoblee, Hull, Yorkshire; chemical manufacturers.

L. L. (Design).—No. 380,806. Photographic chemicals. Levinstein, Ltd., Crumpsall Vale Chemical Works, Blackley, Manchester; chemical manufacturers.

REGISTRATIONS RENEWED.

KODAK.—Nos. 154,843 and 154,850. By Kodak, Ltd., in 1891. (Classes 1, 15, and 39.)

KODAK.—No. 155,009. By Kodak, Ltd., in 1891. (Class 8.)

J. H. DALLMEYER (LONDON).—No. 269,754. By J. H. Dallmeyer, Ltd., in 1905. (Class 8.)

TOSIX.—No. 270,620. By John J. Griffin and Sons, Ltd., in 1905. (Class 1.)

TRADE MARKS REMOVED FROM REGISTER.

In the official language of the "Trade Marks Journal" the following trade marks have been "removed from the register through non-payment of renewal fees." Such non-payment is, of course, the method adopted by a firm having no further occasion for the use of a mark:—

SINNOX.—Nos. 269,073 and 268,993. Registered by Messrs. Marion and Co., Ltd., in 1905. (Class 1 and 8.)

BIORAVURE.—No. 269,014. Registered by the Rotary Photographic Company in 1905. (Class 39.)

New Books.

MORE FIGURES, FACTS AND FORMULÆ.—It seems not so very long ago that the "Photo-Miniature" devoted an issue—and a very useful issue it was—to collecting a miscellany of those facts, hints, formulæ, figures, and tables, which are in common use among photographers, the things which everyone now and again has need of and is glad to find within the compass of so compact a volume as our little New York contemporary. And now Mr. John A. Tennant has issued a companion volume containing a selection of similar subject matter which has been published since 1915. The contents include tables of depth of focus, hints on copying and enlarging, tests for developers, formulæ for developing, fixing, intensifying and reducing solutions and many other practical paragraphs dealing with such branches of work as epi-toning, mounting and colouring. At present we believe the "Photo-Miniature" can be obtained only by sending English postage stamps or international coupons to the value of 35 cents. to Tennant and Ward, 103, Park Avenue, New York, U.S.A.

New Materials, &c.

WESLEM PASSE-PARTOUT FRAMES.—Messrs. Witt and Westley, Bank Chambers, Finsbury Park, London, N., send us some specimens of the ready-made passe-partout frames which they are now introducing to the notice of professional photographers, and at what appear to us to be exceedingly moderate prices. The frame, when hung on a wall, presents the appearance of a passe-partout made in the ordinary way, but Messrs. Witt and Westley have hit upon a very simple plan whereby the photograph can be inserted in the finished frame. This they do by leaving one side, either the top or bottom, of the backing card unattached to the glass, the binding strip of this portion being affixed to both sides of the glass. Thus the print can be slipped between the glass and the backing card and placed in position by manipulating it with the ball of the finger through a hole measuring about 1 in. by 2 ins., which is made in the backing card. It may be thought that there will be difficulty in inserting a print anything like the full size of the glass into a passe-partout made in this manner. Therefore, it should be explained that the frames are not intended for such full-size photographs, but for those of a smaller size than the frame which is provided with a mask, behind which the photograph appears. Messrs. Witt and Westley

use exceedingly nice combinations of colour of mask and binding strip, so that the whole effect in both styles in which the frames are issued is extremely artistic. These two styles are brown (dark brown binding strips and buff mask) and grey (dark grey binding strip and white mask). They are made in two sizes—one 6½ ins. by 4½ ins., with oval opening of texture art paper to take a postcard or cabinet print, and in 10 by 8, to take a whole-plate print. The respective prices are 4s. and 16s. per dozen. Photographers, we think, will be very pleased with these very well-made and artistic patterns of the passe-partout frame. A sample frame is offered by Messrs. Witt and Westley to bona-fide professional photographers.

CATALOGUES AND TRADE NOTICES.

THE INQUIRY MADE by a correspondent some little time ago for "Arco" frames has brought to our table the full price-lists of these and other frames made by Messrs. Whitehouse, Willetts, and Bennion, Ltd., Rex Works, Tything, Worcester. Their series includes all descriptions of metal and wood frames, the "Arco" series being those of plain, narrow, metal pattern, with, in one variety of the series, neat ornamentation at the corners. The firm also makes untarnishable metal frames in a great variety of patterns—oval, square, midget—and in a large range of sizes.

MESSRS. CHANCE BROS. AND CO., LTD., Glass Works, Smethwick, Birmingham, have just issued a price-list of optical glasses now being manufactured by them, and comprising a very wide range of crown and flint glasses, light and dense barium crowns, extra light, dense, and very dense flints, together with many others, the full optical properties of which are specified in the catalogue, which also gives indications of the liability of the glasses to tarnish or to undergo change with time. It is evident that Messrs. Chance have gone a very long way in replacing the optical glasses made by the Jena firm of Schott, and we have no doubt that with the less engrossing demands now made upon them they will be able to give the British opticians all the glasses they want.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, MARCH 24.

Bradford Photographic Society. Annual meeting.
City of London and Cripplegate Photographic Society. "Bromoil." G. B. Clifton.

TUESDAY, MARCH 25.

Royal Photographic Society. "The Photographer's Pencil." C. A. Hackman.
Halifax Scientific Society (Photographic Section). Slide Exhibition at Harrison Road.
Leith Amateur Photographic Association. "A Trip to Lakeland." C. S. McCabe.
Hackney Photographic Society. "A Country Cottage." (Prints.)
Chelsea Photographic Society. "The Thames from Richmond to Oxford." H. Felton.
Manchester Amateur Photographia Society. Monthly Exhibition: "Landscapes."

WEDNESDAY, MARCH 26.

Croydon Camera Club. "Useful Odds and Ends." W. F. Slater.
Ilford Photographic Society. "To the Land of the Midnight Sun." W. Sanderson, J.P.
Dennistown Amateur Photographic Association. Mock Trial.
Photomicrographic Society. "Polarised Light as applied to Rock Sections." C. H. Caffyn.

THURSDAY, MARCH 27.

Liverpool Amateur Photographic Association. "Photography in the Great War." A. D. Pyke.
Brighouse Photographic Society. Exhibition of Members' Prints and Slides.
Camera Club. "Some Apparatus for Aerial Photography." Major Charles W. Gamble, R.A.F.
Hammersmith (Hampshire House) Photographic Society. "Telephotography." Dr. C. A. Swan.
Hull Photographic Society. "Members' Slides and Paget Colour Slides." Secretary.
Rodley and District Photographic Society. Members' Night.
Wimbledon Camera Club. Monthly Print Competition.
Richmond Camera Club. Annual Competition.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, March 18, Mr. W. B. Ferguson, K.C., in the chair.

Mr. Newman F. Horne gave a demonstration of the finishing of bromide prints, and very admirably showed the manipulation adopted by himself in working up bromide prints and enlargements by the powder process—that is to say, by the application of crayon

powder. He made a great point of having the print firmly though temporarily attached to a sheet of glass, which allowed the work to be done very much better. For temporarily attaching the print he used the broad gummed paper binding sold as a substitute for string in tying parcels. The Conté crayon powder, as purchased, produced an intensely black deposit on the print, much blacker than could be got by using black lead, and with the advantage that it produced no metallic lustre. But in order to make it easier to moderate the depth of deposit, he prepared mixtures of the crayon powder and flour pumice of various strengths down to as low as 1 per cent. That is to say, he mixed the crayon powder with flour pumice in the proportions of equal parts, 1:5, 1:10, 1:20, 1:50, 1:100. Even the mixture containing only 1 part of the crayon to 400 parts of the flour pumice when rubbed over the print produced a tint which was scarcely visible when put on, but became so when parts of it were rubbed off, as in introducing white accents into the high-light portions. The flour pumice could be bought from the artists' dealers, or obtained at a very much lower price from the firm of Palmer, of Old Street.

In order to prepare a print, either glossy or matt for working up, the surface was first rubbed down with the flour pumice, applied with a stiff brush. Glossy prints would, of course, require longer treatment than those on matt paper. In the case of rough papers, such as Kodak Royal, it was necessary to use a softer brush in order to avoid rubbing off the silver deposit from the raised portions of the texture of the paper. In then proceeding to apply the crayon, it was his practice first to put a tint of the lightest mixture (containing 1 per cent. of crayon) over the whole surface with a wad of cotton wool. Shadow portions or other parts which required to be strengthened could then be treated with mixtures containing more crayon. In putting in stronger deposits the stumps of leather or paper were used. At any stage the work could be removed with india-rubber or with the material sold as plastic rubber by the artists' dealers. Mr. Horne preferred to use this latter as a fine point when removing the crayon from small outlines in the photograph; even a touch with the plastic rubber point removed the powder as though by absorbing it. In using ordinary rubber for the same purpose, a little coarser pumice powder, sold as grade 90, was used on the rubber. He had found the pencils sold for working up bromide prints of not the slightest use in comparison with the facility with which the Conté powder could be used. The powder was taken up on to stumps or cotton wool from "palettes" consisting of chamois leather fixed to a pair of small hinged boards, each measuring about 4 by 2 inches. When not in use, the two boards were folded with the leather surfaces in contact, and thus preserved the powder which still adhered to the leather from access of dust.

Dealing with the use of sepia powders, Mr. Horne employed the two commercial powders of this kind—namely, those of Conté and Winsor and Newton. They differed to quite an appreciable extent in colour, and thus by mixing them together in varying proportions the colour of any sepia-toned could be readily matched. As in the case of the black powder, he made up mixtures in which the crayon was diluted with flour pumice. For working up bromide prints of bluish colour, produced by development with amidol, a very small trace of ultramarine could be added to the black Conté powder.

Mr. Horne proceeded to deal with the treatment of bromide prints by scraping. He had used nearly all the knives sold for the purpose, and found that of Mr. T. S. Bruce a very satisfactory pattern. The chief essential was that the knife should be kept absolutely sharp by frequent stropping on a leather strip treated with razor paste, and that the print should be quite dry. The very sharp pen-nib print trimmers made admirable scalpels for scraping prints.

When fixing the worked-up print by holding it an inch or two from the steam of a boiling kettle it was found that the original surface of the print, whether matt or glossy, was restored, and in the case of a glossy print with some slight addition of gloss. Although he had tried, he had found it impossible to damage the print by melting the gelatine in this process.

A further method of working up, and one which he used in supplement to that with the crayon powder, consisted in the use of a solution of nigrosine spirit black, dissolved in alcohol, with the

addition of 10 per cent. of chloral hydrate. The latter, by reason of its solvent action on the gelatine, enabled the emulsion surface to take the colour firmly. The work thus put on had the good feature of drying matt on matt prints and glossy on glossy prints, and though it could not possibly be rubbed off, it was removed in an instant by going over it with a rag moistened with alcohol. Mr. Horne showed examples of its use in conjunction with the powder process, and instanced the good use which could be made of the two in conjunction for working up prints which were required for half-tone reproduction. He dwelt briefly, and in conclusion, on working up with mequill and wax as mediums for pigment, referring to the formulae for the latter of Mr. A. V. Godbold, which he had lately been using, and which, while appearing to have many great advantages, required, he found, subsequent treatment in order to remedy the effect of the process in giving a slightly greater gloss to the parts of the print which had received the greatest amount of work.

After some discussion, the very hearty thanks of the meeting were accorded to Mr. Horne.

EDINBURGH SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

THE sixth meeting of the session took place on Monday, March 10, Mr. Young in the chair. Further discussion was raised with regard to the holiday closing scheme, and the secretary reported that the result of the postcard ballot showed a majority in favour of a ten days' holiday. This result it was decided to adopt as the decision of the society. Upon one or two motions and amendments, it was at length arranged that all those participating in the scheme should close at one time, and not at different periods, as had been previously proposed; and the actual date was fixed at August 18, and ten days thereafter.

Mr. Robert Burns, A.R.S.A., who had come to give a talk on pictorial composition, and to criticise a number of photographic prints submitted by members, was then introduced by the chairman. Mr. Young said that Mr. Burns had long been interested in photography, and had always been a friend of the photographer and one who appreciated the difficulties under which photographers worked. Mr. Burns, in commencing his address, explained that his father had been a photographer, and that he himself had begun to take an interest in photography at a very early age. With regard to composition, he asserted that there were neither rules nor laws by which good or bad composition might be judged; but that, on the contrary, it was merely a matter of personal taste, and it was in this light that he criticised the prints brought to his notice that evening. His remarks on each print formed a most instructive and interesting talk, and the good and bad points were carefully shown, and the reason given. Vignetted prints, the speaker mentioned, he did not care for, his reason being that thereby many difficulties were overcome—not by facing them, but by shirking them. He proceeded to explain that in a painting there were three kinds of composition, namely, that of colour, of mass, and of line. With the first the photographer could, of course, have nothing to do; and his necessary entire dependence on the remaining two rendered coloured subjects often very deceptive. A print of a boy blowing bubbles, after Millais' famous picture, gave illustration of this fact. The lecturer explained that the main composition of the original painting lay in its colour, and, therefore, such pictures as these were dangerous models for a photographer to base his work upon.

At the close of the criticism questions were invited. Mr. Campbell Harper, referring to the speaker's remarks upon a low-toned photograph which had been pronounced "flat," asked if it were possible to produce such a picture by photography which was not so. Mr. Burns, after some discussion on this point, replied that, while there were always exceptions to a rule, he thought on the whole that flatness was difficult to avoid.

Mr. Swan Watson then asked if there were really no elementary rules of composition upon which a beginner might base his study of the subject. Mr. Burns reasserted his former remark that there were no rules. To illustrate this point, he said that perhaps it might be asserted by some that, at any rate, no picture should contain lines which divided it either horizontally or vertically in

half. While such a basis of composition would certainly be difficult for a beginner to work upon, and as such should be avoided by him, it was, nevertheless, quite a possible basis for any artist of skill. This he illustrated by making a rough sketch of a sea-piece where the horizon line bisected the canvas. By adding a few lines below this, he so split up the lower portion as to make it appear smaller than the upper part, and thus had the effect of lowering the dividing line. Similarly, by adding a few lines representing evening clouds, he again brought the line back to the centre and created a bad composition. He then gave a more daring illustration of the same point in a rough outline of one of his own pictures where a line bisected the canvas not only horizontally but vertically, making four equal rectangles. Composition, in short, was not a law, but a sense of balance; and what seemed good to one might appear bad to another.

Mr. Barrie proposed a hearty vote of thanks to Mr. Burns for his most interesting talk, and hoped that the speaker might again favour the society at some future meeting. This Mr. Burns very kindly offered to do. The meeting then closed.

CROYDON CAMERA CLUB.

The annual rummage sale was held last week, in cinematograph announcement fashion: Controlled by the Council. Directed by Mr. S. G. Klitz, the noted ivory-hammer executant. Supervised by the president, Mr. J. Keane. Assisted by Mr. H. King. Members happily disposed of much apparatus, largely of the knacker's yard order, which, with avidity, was acquired by others whilst under the hypnotic influence of the auctioneer, perpetually lost in admiration at the wonderful quality of the goods he was disposing of.

And the evening went brightly, just as this world, with all its underlying sadness, in the main revolves gaily, but all knew poor "Old Optics" had gone never to return—the last one to wish any evening to be spoilt on his account, one who loved the club well, and in turn was held in the highest regard by all. In feeling terms the president alluded to the loss sustained by the photographic world in general, and the club in particular.

A recognised authority on optical matters, with an extensive and sound all-round photographic knowledge, Mr. Piper's death causes an ugly gap in the club considered impersonally. In a personal sense many friends will keep now only a memory ever fresh. Never speaking at meetings unless compelled, and often compelled; ever ready to assist with advice, and spare no pains in doing so; with mental reflex not of the quickest a paradox might momentarily befit, but pity the originator of any such twisted proposition when thoughts were marshalled; a plucky patient when on his back for many weary months, facing like a true sportsman what all will have to face some day—such was the late C. Welborne Piper, or "Old Optics" as affectionately known at the club.

It seems almost yesterday when an ideal night for an air raid prompted a member to suggest to him that an early train back to Blackheath (an awkward cross-country journey) was eminently desirable. The answer was characteristic: "If you think I am going to allow those contemptible Huns to interfere in the slightest with my arrangements you are gravely mistaken," he said with cold severity. On a previous occasion when returning home he and others had enjoyed to the full a nocturnal Zeppelin, bombs being dropped in close proximity.

Ever difficult to get Mr. Piper on his legs to speak, when by direct request or subtle artifice he spoke words were brief, but always sufficient and to the point. But on one well-remembered occasion he did wax exceedingly voluble. It arose in this way—a "conversational" evening was on, and a member who tries his best to keep things going first declaimed on a subject which previous inquiry had ascertained Mr. Piper knew nothing about. Nevertheless, the dissertation was concluded with an express proviso that everything which had been said was "entirely subject to the full approval of, or correction by, Mr. C. Welborne Piper." The tag caught on, and chats by experts on printing papers, dry-plates, and other things were all wound up with the emphatic reservation alluded to. Poor Piper stood about six tags, and then

the smoulder burst into flame. He rose, took off the gloves, and smote all round the ring the astonished original sinner. A really creditable performance, as delightful as it was unexpected. Would he could repeat it, but that, alas! cannot be, and so farewell, old friend.

THE OPTICAL SOCIETY.

MEETING held Thursday, March 13, the president, Professor F. J. Cheshire, in the chair.

Major Charles W. Gamble, R.A.F., delivered a lecture dealing very comprehensively with the methods and apparatus employed in aerial photography during the war. He traced the stages through which cameras for photography from aeroplanes and airships had passed as the result of development at the hands of those in the Royal Flying Corps and the Royal Naval Air Service, and subsequently by the photographic section of the Royal Air Force, formed after the amalgamation of the two Services. A great deal of what he said in reference to these pieces of apparatus is contained in the article which appears on another page, and which was in preparation at the time of his lecture. But he was fortunate in being able to show to his audience an example of practically every type of camera used by the British Forces in the course of the war, as well as several used by the French and the Italians and a number captured from the enemy. The focal-plane shutter, although by no means a perfect instrument, had been almost universally employed, first on account of the short exposures which could be given, and, secondly, on its facility for use with lenses of different focal lengths on the same camera. On the other hand, its liability to derangement was a serious drawback, but one which was in part remedied as time went on by making the shutter a separate unit which could be withdrawn from the camera and replaced by a fresh shutter. Major Gamble stated that the Germans were the first to adopt this plan.

It was at first assumed that the most rapid plates were the best for the purpose. Although exposures in good light did not require plates of maximum sensitiveness, yet it was desirable to carry out work late in the day and often when the light was poor. Nevertheless, experience has shown that the capacity of the plate for giving a high degree of density was a quality which ranked in importance with the general sensitiveness. The earlier practice was to use orthochromatic plates, which for many purposes possessed a sufficient degree of colour-sensitiveness. The tendency, however, was to adopt panchromatic plates more and more largely, and Major Gamble estimated at the time of the armistice the proportion of panchromatics in use would amount to from 75 to 80 per cent. of the whole. Filters were in many instances made from optical flats, as necessitated by the length of focus of the lenses and the high degree of definition called for in the negative; but good use was made of a film filter placed in the diaphragm aperture. Though liable to damage, they were found to render satisfactory service for a considerable time, although any deformation would impair the definition of the lens.

A large number of lantern slides were shown illustrating different types of camera and fittings, and a further series showed the results obtained in military and naval work, concluding with some of the surrender of the German warships.

A WANT OF INVESTIGATION.—An unusual experience recently occurred to a prominent professional photographer in the suburbs. Being asked by a lady to photograph a children's party, to be held in the early afternoon, he inquired whether it was to be photographed indoors or out-of-doors. "In a very large room with glass roof," replied the lady, on hearing which the job was undertaken, and on the day appointed a heavy 12 x 10 camera and accessories were carried by hand to the address given. The information afforded about the roof proved to be correct as far as it went, but did not include the fact that it was glazed with orange-glass. Despite the prevailing hue the photographer failed to regard this feature in a rosy light, and sadly returned with plates unexposed. Had he been provided with a small camera fitted with a $f/4.5$ anastigmatic lens, possibly the work might have been undertaken on rapid panchromatic plates, but one does not usually carry a reserve of this kind to meet such a contingency.

Commercial & Legal Intelligence.

A RETOUCHER'S CLAIM.—At Greenwich County Court, last week, his Honour Judge Grainger had before him a case in which Emily Florence Warren, retoucher, of Melbourne Grove, Dulwich, sued Gertrude Mayhew, who carried on a photographic business in Sydenham Road, for £3 15s.

Plaintiff said her claim was for a week's salary, a week's money in lieu of notice, and for 5s. deducted "during the strike." On February 13 (she stated) a 10s. note was missed from the cash box at the studio, and she and another young lady were accused and told to "clear out." They went, and a third young lady "came out in sympathy." She admitted she was late on three mornings during the Tube strike, and said the 5s. had been deducted for this.

Defendant said plaintiff had received notice to leave on February 8. Plaintiff: I had given her notice.

Defendant, continuing, said plaintiff lived but three-quarters of an hour's walk from the studio, so the Tube strike could not have affected her.

His Honour: Ah, but people have lost the art of walking, they want to ride every step.

Defendant added that plaintiff did not work out her notice.

In the result, his Honour gave judgment for plaintiff for £1 15s.

NEW COMPANIES.

ARLINGTON CO., LTD.—This private company was registered on March 11, with a capital of £1,000 in £1 shares. Objects: Manufacturers of and dealers in celluloid products, photographic chemists etc. The subscribers (each with one share) are:—P. E. Jeffs, 30 Colombo Road, Hford, clerk; H. O. White, 179, London Road, Kingsten Hill, Surrey, clerk. First directors are to be appointed by the subscribers. Solicitor, G. C. Bingham, Chapel House, E.C.

News and Notes.

THE PHOTO-MICROGRAPHIC SOCIETY.—The next ordinary meeting will be held on Wednesday, March 26, at 7 p.m., at King's College Bacteriological Laboratories, 62, Chandos Street, W.C., when Dr. H. P. Haigh will give a lecture, entitled "The Internal Structure of Metals." Visitors are heartily invited, and cards of invitation may be obtained on application to the Hon. Secretary, J. G. Bradbury, 1, Hogarth Hill, Finchley Road, Hendon, N.W. 4.

MEMORIAL PHOTOGRAPHS.—In the House of Commons, on March 10, Lieutenant-Colonel Moore-Brabazon asked the Secretary to the Treasury whether he was aware that the Imperial War Museum were anxious to include a collection of photographs of all officers of his Majesty's Services, and whether he concurs in the expenditure which such a collection would entail on the public purse? Mr. BAKER: The Committee of the Imperial War Museum have issued a notice inviting relatives of officers and men of his Majesty's Forces who have lost their lives during the war, to present photographs of them for preservation in the Museum. It is not expected that this collection will involve any considerable expenditure, and I do not think that this is a matter on which the Treasury should interfere with the discretion of the Committee.

MESSRS. ROSS, LIMITED, are, we are glad to see, taking the lead among British lens makers in drawing the notice of the photographic public to the achievements of British opticians, as shown particularly by the instruments which have been provided for aerial photography. The Supplement which accompanies the present issue of the "British Journal" cannot be said to overstate the reputation or the latter-day achievements of this British firm, which within a few months will have completed ninety years of existence. With the curtailment of the output of instruments for the services—work which has necessitated a three fold expansion of the Ross factories—the making of lenses for the photographic public can now engage the firm's activities, and attention is drawn to two of the many notable Ross objectives, namely, the Xpres anastigmat of $f/4.5$ aperture, and the Telecentric, the latter a telephoto objective

of unique type, giving anastigmatic definition at a full aperture of from $f/5.6$ to $f/6.8$, and requiring a camera extension of only half its focal length.

A REDUCTION IN PLATE PRICES.—As announced in *Ex Cathedra* a reduction in the price of plates was made by the British manufacturers to come into operation on March 11 last. The reduced price is such that quarter-plates are sold at 3s. per dozen, other sizes undergoing an approximately similar reduction of those which came into force on August 1, 1918. In order to preserve the continuity of the fluctuations in price we may set forth the successive rises and the present reduction as follows, the figures being those for one dozen quarter-plates:—

	s.	d.
Before June 16, 1913	1	0
June 16, 1913	1	3
March 13, 1915	1	6
February 29, 1916	1	10
March 1, 1917	2	3
February 5, 1918	2	9
August 1, 1918	3	8
March 11, 1919	3	0

The present change in price is thus the sixth which has been made since the outbreak of hostilities.

STRIE IN OPTICAL GLASS.—Various types of striae in optical glass, classified on the basis of visible appearance, are described, and photographs shown, in a paper by L. E. Dodd and A. R. Payne, of the U.S. Bureau of Standards, presented to the American Physical Society. Certain of these types are then discussed from the standpoint of their nature and probable origin. A relationship between gas bubbles in the glass and striae is pointed out. The application of pressure to the molten glass is advocated as a preventive, not only of bubbles, but also of those striae associated with bubbles. Another probable source of the more numerous striae is given as the separation of lead, or its oxide, in the lead glasses. Striae having such origin, however, are more localized, near the walls and bottom of the pot, and may be reduced to a minimum in number by proper heat treatment and stirring. It is thought that striae in the more central part of the glass mass in the pot, which are regarded as being mostly associated with bubbles, may be largely prevented by application of pressure, and that thereby the per cent. of good glass may be considerably raised from the present amount of 20 or 25 per cent. of the total melt. The experimental application of pressure is proposed as a special research, primarily of commercial value, but indirectly of scientific value by its possibility of opening the way to the manufacture of the larger lenses free from defect.

DEATH OF MR. G. W. SECRETAN.—We regret to have to announce the death, on March 7 last, at the age of sixty-six, of Mr. G. W. Secretan, of Tufnell Park Road, London, a photographer of long and wide experience, and one who during the past few years had turned his attention with very great success to certain improvements in the processes of development and fixing. Mr. Secretan invented a preparation which he named "Serteka," and which, when added to the amidol developer, imparted to the latter very remarkable keeping qualities. We have no idea what is the chemical nature of this substance, but certainly, as we assured ourselves at the time of its introduction, its addition to the amidol developer renders the latter one which can be kept and used with almost the freedom from loss of energy which is the property of other developers, such as hydroquinone or M.Q. Mr. Secretan also devised a further preparation, sold as "Unsol," for the purpose of effecting economy of hypo by its addition to the fixing bath. Our opinion is that there is less to be said for this preparation than for the preceding, but it may be hoped, in the event of the discontinuance of the sale of these substances, consequent upon Mr. Secretan's death, that the photographic world may learn something of the chemical composition of the amidol preservative. It would appear that it marked the use of some quite distinct compound for the purpose, and publication or even some suggestion of the work which Mr. Secretan carried out might easily lead to still more fruitful results in the same direction.

RETAIL BUSINESS LICENCES.—As from last Monday, the Order made by the Minister of National Service under Defence of the Realm Regulation 8AA, rendering it necessary to obtain a licence before a person can establish a new retail business or a new branch

of an existing retail business, is to be administered by the Ministry of Labour. Forms of application for licences will be obtainable at all Employment Exchanges. The ten divisional councils in Great Britain which have been formed to co-ordinate the work of local advisory committees are being invited to advise the Minister in the administration of the Order.

Inquiries regarding licences should be addressed to the Secretary (New Business Licences), at the following addresses:—

London and South-Eastern (City and Metropolitan Police District, Kent, Surrey, Sussex).—Hotel Windsor, Victoria Street, London, S.W. 1.

South-Western (Gloucester, Wilts, Dorset, Somerset, Devon, Cornwall, Hants, Isle of Wight).—51, Union Street, Bristol.

Yorks and East Midlands (Notts, Yorks (excluding Cleveland), Derby (excluding Glossop and New Mills), Lincoln).—Harewood Barracks, Woodhouse Lane, Leeds.

West Midlands (Staffs, Shropshire, Hereford, Worcester, Warwick).—Queen's College, Paradise Street, Birmingham.

South Midlands and Eastern (Norfolk, Suffolk, Cambridge, Oxford, Huntingdon, Bedford, Berks, Bucks, Northants, Leicestershire, Rutland, Herts, Essex).—80, Westbourne Terrace, Paddington.

North-Western (Lancashire, Cheshire, Derbyshire (Glossop and New Mills District), Isle of Man).—New Arts Buildings, Liverpool.

Northern (Northumberland, Durham, Cumberland, Westmorland, Yorkshire (Cleveland District)).—47, Pilgrim Street, Newcastle-on-Tyne.

Wales (all Wales and Monmouthshire).—27, Bute Street, Cardiff.

Scotland (all Scotland).—15, Athol Crescent, Edinburgh.

Correspondence.

CINEMATOGRAPH OR KINEMATOGRAF.

To the Editors.

Gentlemen,—In your issue of March 14, Mr. Travers J. Briant doubts whether I am correct in asserting that it is usual in English words derived from Greek ones beginning with or containing "k" to convert that letter into a "c."

I have taken the trouble of classifying all the words beginning with "c" and "k" in a moderately large encyclopædia, which should afford a fair test, and find, as a result, that the Greek "k" is changed into "c" in no less than 94.7 per cent. of cases.

Mr. Briant has simply discovered a few of the exceptions that prove the rule, and is trying to make a rule of the exceptions—while, by the way, mostly belong to the Hanoverian period.

There is an interesting anecdote in Hopwood's "Living Pictures," tending to show that the future builder of the Anglo-French *entente* (Edward VII.) instinctively did not like the look of the prefix "kine." Speaking of the early motion picture apparatus invented by Mr. Birt Acres, the work states: "Brought out in January, 1896, as the 'Kinetic Lantern,' this term was abandoned the following March in favour of the name of 'Kineopticon.' Being called to give an entertainment before the Prince of Wales in July, the inventor found, to his surprise, that the programmes issued under Royal auspices referred to his invention as the 'Cinematoscope.' What could a loyal photographer do except follow the same course, as Mr. Acres actually did? Cinematoscope it was by Royal dictum, and Cinematoscope it remains to this day."

I have hitherto purposely abstained from dealing with the question of pronunciation, which is really irrelevant. The vast majority of people pronounce cinema as "sinema," thereby probably settling the point for dictionary-makers; but there is no valid reason why those with a liking for originality should not pronounce it as if it began with a "k." There are two different ways, for instance, of saying "Cicero," and, if we must make a choice of

evils, a variable pronunciation is much less objectionable than a discrepancy in spelling.—Yours faithfully,

A. LOCKETT.

THE ASSISTANT QUESTION.

To the Editors.

Gentlemen,—I should like, with your kind permission, to tell your correspondent "E. F." the reason why master photographers pay their assistants the low wages they do. Master photographers may be grouped roughly into three classes, which I place in the order of their importance as employers:—A, the man who is in the business solely for the profit he can make out of it, who usually runs several establishments, and is rarely a practical workman himself; B, the higher-class man, whose vanity is such as to prevent his systematically making money as A, who squeezes the ball, strikes attitudes, and exudes phrases, while the staff turns out the work; C, the general pettifogger who, though he may be taken more seriously as a photographer, scarcely counts as an employer. These men, whatever their system, or no system, of business may be, are out for profit, and their profit is obtained by selling as many bits of glorified cardboard to as many fools as may be found to buy them; the fact that Mr. A picks up half-crowns in East London as quickly as a boy finds pebbles on a sea-swept shore, or that Mr. B pockets guineas in the West as deftly as a girl plucks flowers in spring, is no earthly reason why they should share the booty with that quite unskilled and rather shiftless trio—Mr. Washout the "operator," Miss Washeye the "retoucher," and Mr. Washup the "printer."

Your correspondent suggests that "the profession should be taken in hand and modelled on the organisation of the chemists and druggists"—really, the humour of the thing appeals to me. To begin with, how can you possibly organise such detached individuals as Washout, Washeye, and Washup? All three are against one another, and each of the three tries to curry favour with the "boss" at the expense of the other two; Mr. Washout grumbles at Mr. Washup's prints, and Mr. Washup growls at Mr. Washout's negatives; while Miss Washeye, with a woman's weapons, scores against them both!

Then, Mr. Washout and Miss Washeye, at all events, are quite superior persons, who could not possibly be mixed up with trade unionism and the working-class, and it should always be remembered that Mr. Washout's ambition is not to strengthen his position as a paid servant by combination with his fellow-workers, but, rather, to blossom out as Mr. C, with the ultimate hope of exploiting his late confrères à la Mr. A, while Miss Washeye, supposing all matrimonial chances to have failed, is supported by the hope of some day opening up as Miss B, and using to her own advantage the labour of Washout and Washup! Washup alone in this respect is a doubtful starter and possible trade-unionist; of taciturn mood, his ruminations in the ruddy depths are known only to himself and the sable demons that possess him.

Technical education? Imagine an emancipated Washup, his poor head full of symbols and equations, being content to spend his life in a black cellar performing his old trick:—6068, one, two—stop! One, two—stop! One, two—stop! 6069 (bit denser), one, two, three—stop! One, two, three—stop! One, two, three—stop! And so on. Flash up! Drop more bromide! Hang back? Warn your developer! Skill! Why, girls in their teens can do it, and do do it. Picture Miss Washeye having mastered facial anatomy and being proficient in (say) drawing from the antique, coming back to pore over Mr. Washout's atrocities! Gentlemen, it can't be done.

The whole thing lies at bottom in the hands of the blockhead public. So long as it is satisfied with West End piffle and East End smudge work, turned out by children and duffers, so long will things remain as they are; employers will not study their profession with a view to the production of true portraiture until they are forced to, and they will not pay such wages as will make qualification on the assistant's part worth while until the standard of the craft is raised to such a pitch that it cannot be run by boys and girls and certain indefinite persons, who, without a shadow of justification, imagine themselves to be artists.—Yours very seriously,

London, S.W.

SIMPLE SIMON.

To the Editors.

Gentlemen,—Within the space of one long life photography as a means of livelihood has had its birth, adolescence, and arrived at full maturity. Like all modern industries, where it has been possible, it has been developed on modern capitalist lines. The recent statement of a member of a North Country Master Photographers' Association that he was in photography purely as a commercial speculation confirms this, and there are other well-known instances.

The "B.J." some few years ago, in recording the death of the owner of many studios devoted principally to the production of cheap oil paintings, told us the number of thousands of pounds a year which he made out of it. While doubtless many of us would do the same if we only knew how, the fact remains that it is the personal worker rather than the capitalist to whom we must look for the advancement of photography so far as portraiture goes, and also for the fostering of those relations between photographers which make for what we call the professional spirit as distinguished from that of the trader.

On the purely technical side, the improvements will probably come from the laboratory of the photographic material manufacturer and the workshop of the maker of scientific apparatus; but even here it will be the individual experimentalist rather than the proprietors who will make the discoveries, though no doubt the run of a well equipped laboratory such as is at the disposal of Dr. Mees will render possible research work that could not otherwise be undertaken.

For these reasons therefore it is the personal worker who needs to be kept on his feet, whether at the moment he happens to be working direct for the public, or as an employee of some one else.

Membership of the P.P.A. must, of course, be open to all employer photographers engaged in trading on their own account whether mere commercialists or men with a little more idealism like Mr. Adams, but it is quite evident that that body can do very little officially in the way of organising tuition or training of assistants.

What I think should be done is that Mr. Adams and a few people like-minded, not necessarily all employers, should get in touch with each other and exchange views.

In any case there is certainly a need for an association consisting of employees only, the members of which should automatically cease to belong to it (except perhaps in an honorary capacity) directly they ceased to be employees and joined the ranks of independent workers and employers. At the moment the organisation of a trade union on fighting lines is neither possible nor necessary, though if the period of increased trade prosperity—promised for "peace" time, but hardly as yet in sight—fails to materialise, there is no knowing how soon a body able to negotiate on behalf of its members may be required. Before the war there were at intervals of a few years two or three strong attempts to form such a union, the last of which only just failed, and that mainly I think through the defection of the originator of the agitation.

When a meeting was called in London I gave my printer carte blanche to attend, say what he liked, take what office he liked, etc., and he brought back word that only about a dozen (all men I think) attended, and they seemed afraid to open their mouths. A London acquaintance of mine (Mr. Frank Colebrooke), not unknown I believe to the editors, was some time ago successful in organising the employees of an industry allied to photography, and I suggest that if he and a few brainy assistants were to put their heads together, some representative organisation of photographic employees might be brought into existence which would be able to assist such little groups of employers as Mr. Adams might succeed in rallying round him. Several months ago, before this correspondence began, I had it on my mind to write to Mr. Adams, "Thermit," and a few other of your correspondents on the desirability of getting into touch with each other and exchanging views, being convinced that the personal worker needs the help to be got from association with his fellow workers to "keep his end up."

About twelve months ago I mentioned the question of organisation of photographic employees to Mr. Colebrooke and gathered from him that others had done the same thing, but nothing apparently has happened.—Yours truly,

LOOK FORWARD.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed or reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

W. S.—The Professional Photographers' Association, of 89, Albany Street, London, N.W. The fee for membership is 5s.

J. H.—We do not know a firm supplying the particular kind you want, but you might try Mr. J. Elliott, Parade Works, Nottingham.

A. P.—Aprons and overalls of rubber or waterproof material are supplied by the Altrincham Rubber Company, Altrincham, Cheshire.

D. R. H.—The stains are evidently due to imperfect fixation. There is no means of removing them. You should make it a practice to pass all prints through two hypo baths in succession.

H. M.—Machines for perforating numbers which are used for paper, but presumably can be obtained suitable for perforating film, are supplied by E. M. Richford, 9, Snow Hill, London, E.C.

F. H.—We are certainly of opinion that prices of cameras are not likely to fall within the next six months. We think it more likely that new models which may be produced this year will be higher in price than those at present on the market.

C. T. M.—The best solution for cleaning developer stains from porcelain dishes is one of potassium permanganate, say 5 or 10 per cent. in strength, with a fair amount of strong sulphuric acid added. This can be used repeatedly until exhausted.

G. W. Wilson.—There is a complete file of the "British Journal" in the Library of the Patent Office, 25, Southampton Buildings, London, E.C. You can consult it there without any formality and with more facilities for making notes than we could offer you at this office.

An ASTRA.—Your room is not very well adapted for a studio, but will, we think, give fair results if you put in glass, making the skylight about 6 ft. wide and 9ft. long. We do not think you will do much good by trying to work through the doorway. It will be better to get a short focus lens, say 8½ ins., for cabinets, and work along the studio in the same direction as for half-lengths and heads.

K. E.—So far as we know, protection under the 1911 Copyright Act is not obtained automatically in Canada as it is in the case of some other British dominions, such as Newfoundland. That being so, the only course is to apply to the newspaper companies, pointing out that the photographs are your original productions. You might threaten legal action; but if the people know the law of the matter (as they probably do), they will be inclined to resist any claims, whereas they might admit the moral justice of your claim if made amicably.

G. T.—Dry-mounting by means of a flat-iron is something of a makeshift, but you ought, nevertheless, to be able to get satisfactory adherence without markings. One of the best irons for the purpose is that sold for ironing billiard tables, having rounded edges, which avoid marks on the print. A sheet of stout paper, such as

is used for typewriting, is sufficient protection between the iron and the print. As regards temperature, with most tissues the iron is sufficiently hot if you can just bear to touch it for an instant with the tip of the finger.

(1) R.—The best and most customary method is to have the titles set up in type, or if type is not available to draw them on a large scale, and then to photograph down to the required size on a process plate—of course, photographing a considerable number of titles on the one plate. The title strips are then cut through to the glass, and the negative (when dry) stripped off on to the landscape negative by means of hydrofluoric acid. A touch of gum will hold the strip in place, and it is further fixed by the varnish, which is usually given to view negatives.

DOROTHEA.—There are a whole series of soft-focus lenses by American makers, namely the Portland, for which Messrs. Sinclair are the agents here, the Verito for which Messrs. Butcher are agents, and the Smith which, so far as we know is not sold in this country. But you need not buy an American lens if, as you say, you would prefer one of British make. Of these there is the Dallmeyer portrait lens and the Cooke portrait lens, both of which are provided with an adjustment whereby a certain amount of diffusion can be introduced.

M. J.—You will have to get a licence to start a new retail business, but we should imagine that no licence is necessary if, as we assume, you have bought an existing business. However, you could satisfy yourself as to this by application to the office which relates to the West of England, and is situated at 5A, Union Street, Bristol. If you do not carry on the business in your own name you will, of course, have to register the business at the annual cost of 5s. Particulars from the Registrar of Business Names, 59, Russell Square, London, W.C. 2.

MARCELLA.—It is quite true that lenses marked with the same *f*/No. and in fact having actually the same relative aperture are not necessarily identical in speed. The thickness of the glass and the number of surfaces of the lens components which are exposed to the air affect the rapidity though not to a very great extent. There are, however, no comparative figures published relating to lenses on the market, and for practical purposes, certainly in the case of lenses all of modern type, you can afford to neglect the differences. A paper on the subject, which is a partial study of the question, is that by Mr. R. W. Cheshire, published in the "B.J." for August 2 and August 23, 1912.

M. N.—Extra focal length is a term applied to the distance from the object to a point within one focal length of the lens, and similarly to the distance from the image to a point within one focal length of the lens. For example, when copying same size there will be one extra focal length in the direction from the image towards the lens, and likewise one in the direction from the object towards the lens. By thus, as it were, leaving out the consideration a focal length on either side of the lens, the optical calculations in copying or enlarging become greatly simplified. For a further explanation you may refer to an article, "Some Simple Lens Arithmetic," in the "B.J." of June 8, 1917, obtainable from our publishers, price 4½d.

H. M.—The prints have all the appearance of having been fixed in a hypo bath that was acid, or became acid by fixation of a large number of prints in it. In our experience self-toning paper, in order to obtain a thorough permanence, requires to be fixed in a bath which has been made alkaline with ammonia or carbonate of soda, or, perhaps better than either, with sodium bicarbonate. Also, it requires to be frequently renewed or further dosed with alkali in order to neutralise the acids which are dissolved out of prints. At the same time we are bound to say that your prints strike us as exceptionally bad specimens of fading.

T. E.—Various preparations have been patented or introduced for the purpose. One such, of French origin, also contained the developer, and was compounded of—

Magnesium picrate	81 parts.
Sodium sulphite (anhydrous)	544 parts.
Sodium hyposulphite (hypo)	250 parts.
Diamidophenol	125 parts.

This powdered mixture was dissolved in water to the extent of about 4 gms. per 100 c.c.s. (about 20 grs. per ounce), and the

exposed plate or print having been placed in it in the dark, the further operation could be continued in daylight or other actinic light. None of these mixtures have come into practical use.

B. J. PYRO-SODA.—We see in the instructions for making the pyro-soda developer by the "B.J." formula the item that the mixture of soda sulphite and metabisulphite after dissolving should be boiled for a minute or so. As we make up this developer in large quantities and have good cause to be grateful to it for the freedom from stain on both negatives and prints, we should be glad if you would tell us whether there is any real advantage in boiling the mixture. In making up the solution by the gallon it is an inconvenience to have to boil, and if there is no really good object served we should be glad to dispense with this part of the preparation.—C. F. G. Co.

If you do not keep the stock solution for any great length of time, say for not more than four or five weeks, there is no advantage whatever in boiling the mixture of metabisulphite and sulphite. At the same time you should preferably dissolve these salts in boiling water, that is boiling water poured on to the dry mixture. There is no necessity to boil the full amount of water specified in the formula. Enough to dissolve the salts is sufficient.

SULPHITE TROUBLES.—I am dissatisfied with the tones which I get by the regular method, using the bromide-ferricyanide bleach and toning with sulphide. What I should like to get is a tone similar to what one sees on the postcard portraits in the shops of the Rotary Company. I work, as I think, exactly to instructions, well washing prints between bleaching and sulphiding, but perhaps there is some matter of importance which you will be able to mention for my assistance.—T. W. D.

The commercial cards which are sold by the stationers are most of them toned by the hypo-alum method, which gives the characteristic purplish sepia which is the preference of the postcard printing trade. Dependent on the brand of paper which you use, the bleach-and-sulphide method yields tones which are more brownish and, as we think, more pleasant. If the results are poor in tone the most general cause is insufficient development of the prints in the first instance. See our note last week under *Ex Cathedra*. There is no need to give more than a couple of minutes' washing between bleaching and sulphiding. To wash for a longer time may give prints which are less satisfactory in colour.

Line Advertisements.

Charges for Insertion.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind the scale of charges. They will thus save themselves delay in the publication of their announcements. A Schedule by which an advertisement can be correctly priced will be sent on request.

Net Prepaid Line Advertisements.

12 words or less	1/-
Extra words	1d. per word.

(No reduction for a series.)

Special Note. Box Number Advertisements.

"Box No." and office address charged as 6 words.
For forwarding replies add 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.
Orders to repeat an advertisement must be accompanied by the advertisement as previously printed.

Advertisements are not accepted over the telephone or by telegram.
The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.

Displayed Adv'ts should reach the Publishers on Monday morning.
The insertion of an Advertisement in any definite issue cannot be guaranteed.

SUMMARY.

We regret to announce the death, on Saturday last, of one of the veterans of photography, Mr. Watmough Webster, at the age of 76. (P. 160.)

In a contributed article Mr. James Graham gives working details for silvering mirrors by means of the process in which the glass is first prepared with stannous chloride and the silver reduced with formaline. (P. 155.)

A lecture by Mr. Newman F. Horne before the South London Photographic Society contains many practical hints from this experienced worker on the use of the chromium intensifier. As an alternative to the use of Farmer's reducer, Mr. Horne recommended bleaching the negative in the ordinary sulphide-toning bleach, washing thoroughly, and re-developing only to the required degree with amidol. (P. 166.)

A number of useful hints on the making of enlargements, including the production of soft effects from negatives of normal definition, are contained in an article by Mr. J. W. Doubleday from "Camera Craft." (P. 158.)

A few of the maxima which require to be observed in development are the subject of an article on page 154.

Some particulars of the measures being taken for the manufacture in this country of photographic raw paper base are quoted from the recent prospectus of Messrs. Wiggins, Teape. (P. 160.)

A few of the additions to his regular business which may appropriately be made by a photographer are suggested by Mr. E. M. Spiers. (P. 158.)

The article this week by "Practico" is a talk upon the considerations which should govern the arrangement and furnishing of the reception room. (P. 156.)

An interesting exhibition of photographs by Dr. O. Atkin Swan, President of the Royal Photographic Society, is now open, until April 5, at Hampshire House, Hog Lane, Hammersmith. (P. 161.)

Apparatus for the development and drying of cinematograph film is among the patents of the week. (P. 162.)

In the production of new styles of photographic print the transfer bromide papers can render good service. (P. 154.)

The use of a vest-pocket camera as a substitute for the bulkier instrument necessitates due caution against over-development of the negative. (P. 154.)

In making enlargements from very flat negatives good use can be made of the extra slow daylight papers in conjunction with a high-power light-source. (P. 154.)

EX CATHEDRA.

Enemy Cameras. We are glad to see that our contemporary, "The Photographic Dealer," is actively interesting itself to put a stop to a species of trading with the enemy which, though small in amount, is nevertheless quite indefensible. It appears that in Cologne and other places in the occupied portion of Germany cameras of German make can be bought at not a very much higher price than that before the war, yet one which at the greatly depressed value of the German mark enables the buyer to dispose of the camera at a good profit on bringing it to London. It is stated that dealers in London are being asked to purchase these instruments. The Photographic Dealers' Association has taken the matter up, and it may be hoped that prompt measures will be taken to see that this illicit trading is speedily stopped. There can be no objection to Army officers in the occupied country buying such photographic supplies as they want from the only available sources, namely, the German dealers, but the practice of snatching a paltry profit by bringing the cameras to London for sale is one which surely should be immediately prohibited by the authorities on their notice being drawn to it.

Cycle Portraits. We were recently shown a most artistic portrait photograph of a feminine client of a professional friend. The lady was riding her bicycle along a delightful stretch of country road. The portrait was a really delightful piece of work, and showed to perfection the poise of the head, the easy carriage of the rider, together with the perfect grace with which some women have learnt to cycle. This is an idea that might be well worth following up, for if well done a portrait of this kind should be a good business bringer, and is far in advance of the portrait in which a stationary cycle is "ridden" in the studio. The real thing offers no special difficulties in the way of making a satisfactory picture, nor need the operator think that a reflex is essential. A good hand-camera is desirable, but the picture to which we refer was made with an ordinary field camera. In this case the picture was focussed on the ground glass, the cyclist being requested to stand on a certain spot marked with a couple of smallish stones. She then retired, and rode slowly towards the camera for the exposure to be made. It will be found best, if possible, to make the actual exposure while the cyclist is free-wheeling, in order to lessen movement as much as may be, and for this, in order to obtain the best effect, the pedals should be horizontal or at the "quarter to three," the correct free-wheeling position. Rapid exposures are not needed; a 25th of a second at $f/8$ on a bright day with fast plates will be found to give a good negative. There is no reason

why this plan should not be applied to male customers as well, for many persons of both sexes lend themselves when cycling to most graceful and pleasing poses.

Gaslight Enlarging. The trade enlarger, whose work lies not only in the enlarging of negatives of reasonably decent quality such as he obtains from professional photographers, but also those of the quite unskilled amateur, has reason to ignore the advice which is sometimes given, namely, that the speed of modern bromide paper renders the use of a very high-power source of light unnecessary. It is quite true that the practice of some enlargers of keeping an oil lamp for the enlargement of particularly weak negatives on to bromide paper is one which contributes to a greatly improved result; but, on the other hand, a great deal more can be done if a high-power light such as an arc is available, and the enlargement made on one of the extra-slow gaslight papers, such as Cyko or New Kodura. The degree of brilliancy which in this way is obtained in an enlargement from an utterly miserable negative requires to be seen to be believed, and we have known of enlargers denying the making of such results except by the production of a new negative. The amateur enlarger can obtain them with his customary apparatus if he is prepared to let exposures run to as long as half an hour, but for commercial work a light of the power of an arc or mercury vapour is, of course, a necessity.

Quality of V.P. Negatives. Now that there is an ever-increasing tendency on the part of Press, commercial and professional photographers and serious amateurs towards the use of vest-pocket cameras, many are finding out that their technique is decidedly faulty. It is certainly easier for the less skilful to make technically perfect 12 by 10 negatives than to produce an equally good result from a vest-pocket size negative via enlarging. The ideal result depends mainly upon the worker knowing what kind of negative to aim for. The general tendency is to make these negatives too dense, and if this is the case, of course, the enlarging process will be found to make harsh contrasts all the harsher, and to lose the fine tonal qualities of the negative. It would be a good plan for the photographer who contemplates using a miniature camera as a supplementary instrument to make half a dozen exposures by the aid of the meter, taking care that these are on the full side and to develop them so that each is slightly further developed than the previous one. A set of enlargements from the negatives will show exactly what is required. Great care is needed to prevent mechanical damage, such as scratches, etc., and we favour the tank and time method of dealing with the exposures made with vest-pocket cameras. Grain must also be avoided, but with a suitable developer, used fairly diluted, this ought never to prove troublesome.

Transferred Bromides. Now that bromide paper is the almost universal printing medium with many photographers, more attention might with profit be given to the transfer variety, which, if carefully used, may be the means of imparting an individual and artistic expression to photographic work. We can recall a case recently in a large exhibition where considerable attention was attracted by a picture upon one of these papers which was transferred apparently to a brownish paper. The whole effect was most original and uncommon. The other day we noticed some cabinet-sized portraits upon quite large mounts in a certain photographer's show-case. Examination revealed the fact that they were originally made upon one of these papers and transferred to the

mounting paper. A delicate tint was worked in round each print with water-colour, thus imparting a most delightful finish. This offers a considerable saving over the plan sometimes adopted of making the prints upon large sheets of paper and carefully masking off the picture, while the result is to all intents and purposes the same. That the picture is reversed by the transferring has never to our mind been a serious objection to the process, as the average sitter would quite fail to notice it, but if the operator's intention is to use the process in carrying out some definite scheme the plate may be put into the slide, glass side to the lens, and the slight difference allowed for when focussing. The back of the plate should be carefully cleaned, and the film protected from abrasion by the metal dividing plate of the slide. For this there is nothing better than a piece of card covered with black velvet cloth.

RATIONAL DEVELOPMENT.

THERE are many ideas as to what is the correct way of developing a negative, and the exponents of each claim that theirs is the true and only way. There is no accepted standard for goodness in a negative, which is perhaps a good thing, for its absence allows of individuality in the finished result, although this must not be confused with "fluking," which is what happens when an operator aims at one effect and obtains quite another, which he is astute enough to put forward as a premeditated piece of work. The clever photographer is the man who starts with a definite idea for a picture, and by skilled technique realises it in a print. To do this one must have perfect control of exposure and development. The best lighted figure may be made either hard or flat by incorrect exposure, while a correctly exposed plate may be made to yield a thin soft image or a dense harsh one by injudicious development.

To ensure even quality it is very necessary to keep to one brand, and preferably one grade of plate. The best technician in the world could not produce a dozen negatives of even quality from twelve plates of different makes and rapidities even if all had received an equivalent exposure. Plates vary greatly in the time taken for development and in the appearance of the image before fixing. A common way of judging the progress of development is to look for a trace of the image on the back of the plate. This can only be done if one brand of plate is in use, and then only to a limited extent, as this method is quite upset by variations in the thickness of the emulsion coating. While upon this subject it may be useful to correct an error sometimes made, which is, that when the image is clearly visible on the back of the film, the utmost density which the plate will give has been obtained. We had a case under our notice some few months ago where the operator proposed to change his plates, because, although he developed them right through to the back, the images were always thin. On our suggestion he allowed some plates to remain in the developer for three minutes longer than others, which he fixed at his usual time, and was convinced by the difference in density that his development had always been carried on for too short a time.

One of the old errors was that the best results could only be obtained by what was known as "tentative development." This meant starting the development with a minimum of alkali, which was gradually added as needed. There was some reason for this when ammonia was used as the alkali, as volatilisation rapidly reduced activity of the solution, and fresh ammonia was needed to complete development. When the fixed alkalies in the form of the carbonate of soda and potash came into general use the "working up" by adding small quantities of

alkali to the developer fell into disuse, although a few old-fashioned workers still practise it.

It is not our purpose to recommend any particular developing agent as superior to the others. Some developers have the reputation of giving thin images and others plucky ones, but this is largely a question of dilution and temperature. Next to exposure, which decides the possibilities of the negative, comes length of development with any given solution. With normal exposures short development gives a thin flat negative and long development gives the maximum of density and contrast. Between these extremes the operator must choose for himself. All non-staining developers, such as amidol, hydroquinone, and many others yield a negative of which the printing quality is due to reduced silver only, but pyro behaves differently, the silver image being reinforced by the "pyro stain." It is generally acknowledged that a pyro-developed negative will usually give a more brilliant print than one of apparently similar density, but free from stain. This is due to the fact that the stain is deposited in proportion to the density of the image, and is not uniform all over the plate. If such a negative be dissolved away, by using Farmer's reducer, it will be found that a thin brownish-yellow image remains.

One of the commonest errors in development is to over-develop under-exposed plates, and to under-develop over-exposed ones. This is caused in the first place by the desire to force out all possible detail in the shadows, the

result being that the high lights are made so dense that any shadow detail is lost in the necessary depth of printing. In the second case the over-exposed plate is under-developed because the whole surface of the film quickly blackens, and the operator fears that the detail will become buried. This is quite wrong; the proper course is to develop for the full normal time, and to dissolve away the fog with the ferri-cyanide reducer. It may be noted here that it is of little or no avail to add bromide to the developer after the image is well out; to be effective, bromide should be added to the developer before pouring on the plate.

The degree of dilution of the developer has an important effect upon the negative. A weak solution can be used until all the details of an under-exposed plate are brought out, without obtaining too much intensity in the high-lights. Concentrated solutions give the maximum of contrast, especially when a little bromide is used in addition.

Too prolonged development will give a general chemical fog, and an excess of alkali often added in cases of under-exposure has the same effect. A disagreeable colour, not quite a fog, is caused by putting plates developed with amidol or metol direct into the fixing bath without rinsing. With pyro the fixing bath rapidly becomes discoloured, but with the non-stain developers a large quantity of solution can be carried over into the fixing bath without altering the colour very much.

AN EASY METHOD OF SILVERING MIRRORS.

Mirror silvering is an operation which is avoided by most photographers as a process in which the successes are low and for the favoured. After several failures with the tartaric acid-sugar reducing agent for silvering glass, the present writer cast about him for some simpler and more rough and ready method of preparing a reflector for his camera. It has long been known that it is possible to produce silver mirrors by the use of formaline as a reducer. The method, however, has not come into practical use because the deposit of silver is usually so granular that it will rub off the glass upon the least touch. The following formulæ provide a means of silvering glass and other substances with ease and rapidity, and the process is a fascinating one to watch.

Stock Solutions.

Stock Silver.

Silver nitrate	45 grs.	3 grms.
Distilled water	10 ozs.	300 c.c.s.

Stock Formalin.

Formalin (40 p.c. Formaldehyde)	1 oz.	45 grms.
Distilled water	10 ozs.	450 c.c.s.
Methyl Violet dye	10 grs.	1 gm.

These solutions improve on keeping.

The following quantities are sufficient for 20 square inches of glass, allowing for waste silver being deposited on the dish and elsewhere.

Take 3 ozs. (90 c.c.s.) of the stock silver solution and add 10 per cent. ammonia solution drop by drop (a fountain pen filler is handy for this), shaking the mixture after each addition. The mixture first becomes turbid, and then gradually clears. When clear, stop adding ammonia. A slight excess of ammonia is not detrimental. In another receptacle pour out 3 drachms (11 c.c.s.) of the stock formalin solution.

The Silvering Process.

Take the piece of glass it is intended to silver, and clean it well with whiting and water, or by any other method that may

be favoured, and rinse it under the tap, swabbing the surfaces with cotton wool. Now rub the wet face of the glass with another piece of cotton wool which has been soaked in the following priming solution:—

Tin Protochloride (Stannous Chloride) 25 grs.	1 gm.
Water	10 ozs. 200 c.c.s.

Ordinary tap water will do. This solution should be thrown away when done with.

Rinse the glass under the tap and wipe it with a piece of cotton wool which has been dipped in distilled water.

Place the glass face up in a developing dish which has previously been cleaned with nitric acid and rinsed with distilled water.

The next operation is to add the formalin to the ammonio-silver mixture, and immediately pour into the dish, and to rock the dish well.

The silver begins to deposit at once on the primed surface, the solution becoming darker after a short time, and then slowly clearing. After from one to two minutes the solution reaches its maximum clearness, the by-products of the reaction forming into little granules. At this point run tap water into the dish and lift the mirror out and rinse it, finally swabbing with a soft piece of wet cotton wool.

Allow the mirror to drain for a minute or two, and remove any drops of water from the surface by lightly touching them with a piece of blotting paper. After half an hour or so the mirror should be quite dry and ready for burnishing.

Finishing the Mirror.

When dry, the mirror should have a brilliant surface, with a slight yellowish tarnish, which must be removed by polishing if the front of the mirror is to be used as a reflector.

For polishing and burnishing the surface, take a piece of wash-leather a couple of inches square, or, failing this, a

piece of really soft cotton rag, and tie it round a plug of cotton wool, so as to form a medium soft pad. Keep this in an old plate-box with some rouge. The rouge may be bought at a chemist's, or in some households purloined from the feminine dressing-table. Jeweller's rouge is sometimes too coarse. The wash-leather pad should be lightly charged with the rouge.

Warm the mirror and the pad slightly so as to be sure that no moisture is present, and then lightly rub the surface with a rapid small circular motion. The mirror will take a brilliant polish and is then ready for use.

General Consideration.

Practically speaking, the hotter the glass before applying the silvering solution, the whiter and more granular the resulting mirror will be. Cold solutions produce quite a good deposit, which is dark in colour on the surface, but which takes a brilliant white polish. The best temperature is about 70° to 80° F. It is a good plan to have the glass a few degrees warmer than the solutions. This can be accomplished by immersing the glass in tepid distilled water for a few moments before silvering.

Celluloid may be easily silvered by exactly following the procedure as for glass.

Mirrors may be silvered face down if desired. It is a question more of convenience than actual merit.

Silver may be prevented from depositing on unwanted parts by painting those portions with vaseline or celluloid varnish previous to priming with the tin solution.

Spent solutions are hardly worth saving, even when there is a quantity. Most of the silver in the solution comes down as actual mirror surface.

Methyl violet dye has the property of keeping the surface of the mirror brilliant and unclouded. Its action is analogous to that of bromide in a developer. It may be omitted if not available.

The priming bath gives a much more adherent coating. It also has the property of attracting most of the silver to the working surface, instead of too generously distributing it on the sides and bottom of the dish. It is supposed that a silicate of tin is formed on the surface of the glass.* This, however, cannot be the case with celluloid or other non-glass surfaces.

The cost of silvering 20 square inches of glass, reckoning silver nitrate at 4s. per oz., is about 2½d. As failures cost as much as successes, it is a good plan to practise on small pieces of glass before attempting a larger surface. One has, for example, to learn how to clean glass properly.

Well boiled water can in most districts be used instead of distilled water.

As a protection against oxidation, the mirror may be varnished with celluloid varnish. The coating of varnish should not be too thin or it will dry with a smoky surface. No other varnish is suitable for the purpose, because silver reacts with most gums, etc. It is, however, easy to resilver a mirror when the surface is worn away by repeated repolishing that in most cases it is hardly worth while to decrease the efficiency of the reflecting surface by varnishing it.

Measures, beakers, and dishes should be cleaned after use with strong nitric acid, or the remnants of silver will give trouble when the vessels are used for other purposes.

JAMES GRAHAM.

* F. Falet, *Jour. Soc. Chem. Ind.*, 1893, 151.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
The Camera and the Lens (Jan. 10).
Managing the Sitter (Jan. 24).
Backgrounds (Jan. 24).
Studio Exposures (Jan. 31).
Artificial Lighting (Feb. 7).

Printing Processes for Portraiture (Feb. 14).
Studio Accessories and Furniture (Feb. 21).
The Surroundings of the Studio (Feb. 28).
Studio Heating and Ventilation (March 7).
The Postcard Studio (March 14).
The Printing-Room (March 21).

ABOUT THE RECEPTION ROOM.

EXCEPT in the cheapest class of studio, where customers walk in and ask to be photographed in the same way as they would go into a haberdasher's for a packet of pins, the reception-room is one of the most important departments of the whole establishment. The photographer should never lose sight of the fact that he has not only to make photographs, but to sell them, and that the selling has to be done first. In nearly all business concerns the greatest importance is paid to the organisation of the selling department, and the principal salesmen or travellers are the most highly-paid members of the staff. It is so even in a few photographic businesses, for I know of one instance at least where the operator, a very efficient man, received £300 a year while the presiding genius of the reception-room made more than three times as much, while in others the lady receptionists are almost as highly paid as the operator. I do not give these examples to prove that a highly-paid recep-

tionist is a necessity in every studio, but to point out the importance of this department in almost every class of business. As our Transatlantic friends would say, we are not in photography for our health, but to make as good a living as possible, and to this end we must put forward our wares in the most attractive way.

The reception-room should not have the appearance of an office or shop, but as nearly as possible resemble an ordinary room, where people should feel that they can inspect the specimens at their ease, without being hurried in their choice of size and style. I was recently in a reception-room nicely kept, but with hardly room to sit down, the greater part of the space being occupied by two huge roll-top desks, one for the receptionist and one for the proprietor. The selling was all done at a small table against one wall, and the floor space so restricted that if a second sitter came in, he or she and her

friends had almost to rub shoulders with the previous arrivals. This is embarrassing to both parties, as one's portrait is a private thing which is not to be discussed in public, the probable result being that a much smaller order was given in order to have the matter over and get out of the way. In contrast with this, I have seen a reception-room where the prospective sitter was interviewed in a secluded corner, while other visitors waited and looked at pictures in the main part of the room, plenty of comfortable seats being provided. Such an arrangement may not always be possible, but the idea is there, and it should be worked upon as far as conditions allow. In quite a small room a table and a couple of chairs can be arranged for the confidential talk, and all other seating accommodation placed at a judicious distance. Such seating accommodation, it may be hinted, should be kept clear for use, and not occupied by specimens and parcels.

A separate desk or table should be provided for bookkeeping, spotting, or any other work which the receptionist does to fill up her spare time, and, if possible, this should be screened off so that it cannot be inspected by prospective sitters. There is nothing so annoying as to have a friend call upon a sitter and tell her that she has seen her portraits in the course of finishing, adding a few gratuitous criticisms at the same time, while there are inquisitive folk who will not hesitate to quiz at business papers, which one may have the best reasons for keeping private. So lacking in manners are some folk that I have seen a man open a ledger to amuse himself while waiting.

An effort should be made to keep the room as fresh-looking as possible, and distemper or wall-papers should be renewed as soon as they become dingy. The studio is the workshop, and need not be so spick and span, but the reception-room gives the first impression, and that should be a good one. Hot colours should be avoided, cool greys and greens being usually suitable, and harmonising better with the work shown. Furniture should be as light in construction as is consistent with strength, and, above all, chairs and settees should be restful. It is not necessary that great expense be incurred in securing this, for a better effect can often be produced with cane or wicker and chintz than with carved oak and velvet. An effort should be made to show some individuality, and not to follow the beaten track too closely.

All specimens should be kept in good condition, and only up-to-date styles shown. In too many places the walls of the reception-room and staircases are cumbered with enlargements and paintings of the Victorian period, which waste space even if they do no other harm. I sometimes think that the success of some of the more recently established photographers is due to the fact that they exhibit no obsolete stuff. Regarding the loose specimens, these should be scrupulously clean and mounted in the current styles. Mounts change in fashion unless plain papers are used, and the modern public is quick to notice anything which is not quite up to date. All specimens should be kept in some sort of classification, so that it is not necessary to hunt through a heap of prints to find a certain style which may be desirable to bring forward. Specimens which are not often required are best kept in portfolios, carefully classified into such divisions as wedding groups, equestrian portraits, fancy dress pictures, and the like, and when various printing processes are used it is as well to have a set of the various kinds made from the same negative, so that a comparison may be more easily made. The outsider is more likely to be influenced by the subject, and will order from a bromide specimen of a subject which strikes her fancy instead of the more remunerative platinum or carbon.

Miniatures and coloured work should be carefully and appropriately framed, and the price quoted should include the frame. The photographer will then be spared the agony of seeing a delicate water colour on opal, framed in maroon plush, a shock which I have experienced.

The actual selling calls for the greatest tact. It is not sufficient to be attentive and keen on getting a good order; care must be taken not to wound the self-esteem of the prospective sitter. To avoid doing so, the receptionist should carefully abstain from bringing forward any styles which would not be suitable. Thus one should not offer full lengths to a dumpy sitter or profiles to one with a nez retroussé. In the first instance, should the sitter desire a full length, it should be pointed out that the face is then very small, and a three-quarter length suggested. This is much better than hinting that the lady has not the figure to make a full length. In the second case it may be pointed out that a profile, while making a good picture, is rarely a characteristic portrait. If in either case the request is persisted in, care should be taken that other positions are also taken and submitted, in which case the sitter will then discover for herself the fact which she would have resented being told point blank. Every effort should be made to secure a better order than the sitter originally contemplated, but this must be done skilfully and without any appearance of pushfulness. The superior appearance, the guaranteed permanence, or the fact that the picture shown is absolutely in the latest style should be pointed out, and in most cases the desired result will be obtained. The mere mention of the fact that some well-known person selected that style will sometimes do the needful. If the attempt should be unsuccessful, there should be no appearance of disappointment, but the order accepted with the same apparent cheerfulness as if it had been doubled. In many cases a promise of extra positions, with a hint that a re-sitting will be willingly given, will go far to induce the customer to take the better style, but in no case should there be any inference that any less pains will be taken with a small order than with a larger one.

A clever saleswoman—it is rarely a man nowadays—can greatly increase the turnover by the introduction of side lines, such as miniatures, enlargements, and copies. Few people have any idea of the excellent results which can be obtained from old portraits, and I have more than once obtained a good order, in addition to the sitter's own portraits, by showing a very successful enlargement from an apparently unpromising original, such as a faded C.D.V. or an amateur's snapshot. Hundreds of people have small pictures of friends who have fallen in the war, or who have died, without ever visiting a studio, which they would be glad to have reproduced in good style did they realise what was possible in this way. I have taken as much as thirty pounds for portraits of a schoolboy who had only once been photographed, and that in a group. Such work is usually ordered in platinotype or carbon on account of the absolute permanence which can be guaranteed. Many photographers who are not used to a high-class trade fall into the error of quoting too low a price for such work, but it is surprising what people will pay for a good picture of this kind. If it be beyond the power of the photographer to do so himself, he can entrust the work to a first-class trade house and still make a handsome profit. I can recall one case in which an order was taken for a thirty-guinea oil painting from a tiny head which someone had pasted inside his watch case. At least half of this was net profit to the photographer, whose part of the work consisted in making a careful copy and a plain enlargement as a guide for the artist.

I am afraid I have been rather discursive on this subject, but I am desirous of pointing out that the management of a railway ticket office and that of a photographer's reception-room need to be conducted upon different lines, although, perhaps, I am doing an injustice to the tourist agent, for I have seen a clever clerk persuade a would-be traveller to extend his tour by pointing out how much more he could see for only another ten pounds.

SIDE-LINES FOR PROFESSIONAL PHOTOGRAPHERS.

LETTERS have recently been sent in to the "British Journal" containing inquiries as to suitable side-lines which can be worked in connection with photography. Perhaps a few hints from one who has made a study of this subject may be of use, especially to those who realise that this profession is not what it has been, owing to extreme competition, and the consequent degrading of prices. The best class man has nothing to fear. He will hold his own anywhere on the strength of his prestige, but the good middle-class man has a far wider field of rivalry to face, and a bigger army of competitors to fight with weapons easily equalled by theirs.

A profitable and attractive side-line, if selected with good taste, proves not only a help to the funds, but also serves as an appeal to a considerable number of prospective clients who would in the ordinary way have passed the studio by without a second glance. There is no reason why a side-line chosen with care and discrimination should impart a derogatory air to a photographic business, and where some of the highest and most exclusive have led the way, the rest need not hesitate to follow.

In the "Journal" mention was made of one instance in which a firm of Scottish photographers had taken up the designing and making of toys, and another in which a photographer in Kent specialised in the design and manufacture of fancy leather goods, such as calendars and blotters. Of course, such side-lines as these demand a good amount of talent and skill, which, unfortunately, belong only to the few. But others there are which come more within the scope of the less privileged, and amongst such may be mentioned the sale of art ware and pottery, which I have seen exploited by a photographer with success. The supply of picture and miniature frames forms so usual a side-line with photographers that they are only worth a passing allusion, as also are pictures and prints, engravings of worth and lithographic copies of many treasures of art.

One photographer has combined the sale of jewellery with his portraiture, and exhibits precious gems along with his other works of art, much to the general attraction of the showcase, and it may be safely asserted that no delicately wrought piece of jewellery or valuable stone is ever passed by unnoticed, at least by the gentler sex. It goes without saying that this branch of business demands the skilful judgment of an expert.

A lady photographer of my acquaintance, who in years gone by dabbled in art, is now contemplating the idea of introducing as a paying side-line the sale of hand-painted and poker-worked articles suitable as presents to take back by tourists and holiday-makers. She has seen it done elsewhere with astonishing success by a seaside photographer, who kept a table in the reception-room on which were displayed all sorts of hand-painted satin and velvet table-centres, pin-cushions, tidies, plaques, tobacco-jars, blotters, and so on, and amid floral sprays or dainty seascapes were painted the appropriate words, "A present from Saltbeach-by-the-Sea," etc. This "gift" table was kept supplied by members of the photographer's family, and so well was it patronised by trippers and others that even after they had finished their holiday and gone home they sometimes wrote back to order another cushion-cover or painted mat, so much had they been admired by their friends. All visitors to the seaside make a point of two things—to be photographed, and to take home a souvenir, and they would no more think of omitting either obligation than of going without the holiday. So why should not the photographer kill two birds with one stone?

Photography and stationery, photography and a doll's hospital, photography and a branch post office are all combinations I have met with, and although these side-lines might have very little to recommend themselves to professional photographers, they have, I believe, proved lucrative to those who carried them out. For my part, I think it unadvisable to introduce as side-lines anything that does not come under the title of art, as any photography worthy of the name is essentially art, whatever its critics may assert to the contrary, and to harness it to any less worthy branch would seem a breach of harmony. The side-line has a claim on our attention as an advertising agent, adding a novelty and interest to a shop window which otherwise might be lacking, if one is to judge by the mediocre displays of photographs which many of us must have noticed.

Other ideas occur to me on the subject of side-lines, but perhaps enough has now been said to suit the length of this article, and to start others on the track of suggestions which will be likely to prove a lucrative adjunct to a photographic business, and if such is the case my object will have been achieved.

E. M. SPIERS.

SOFT EFFECTS IN ENLARGING.

THE facility and economy in making portrait prints by enlargement are advantages of a system which is growing in favour, and which has a further claim to the notice of photographers—namely, the opportunity which it affords of producing a portrait of diffused definition from a negative of the ordinary character. This is a point which receives special emphasis in some notes on enlarging which we reprint below from "Camera Craft." Their author, Mr. J. Walter Doubleday, describes the particular form of device which he employs in [breaking up to a pleasant degree the definition in the negative.—EDS. "B.J."]

BROMIDE enlarging is steadily growing in favour, even more rapidly than would be the case were only those workers taking it up who are changing from the formerly popular view camera sizes to the present more convenient small type of cameras. I know a number of professionals who are making all their portrait work through the enlarging lantern, not alone for the purpose of securing larger prints than the negatives they care to make, but for the control and speed that the process permits. They have, of course, somewhat modified their apparatus, by eliminating such parts as serve mainly to give a large range as to size, and by adding other fittings that increase rapidity of production.

I have mentioned this, not as an introduction to the subject of apparatus, which I shall avoid, but as a means of suggesting the recognised simplicity and advantage of making prints in this way. Enlarging apparatus is of such varied form, depending upon the light available, the requirements of the user, and to some extent the purse as well, that space does not permit me to do the subject justice if I am to record a few of the things I have learned about

the actual production of bromide enlargements, things common to the work, irrespective of the form of apparatus used. Enlarging on bromide paper is quite simple, the apparatus required is not complicated, and the results have the highest endorsement of our best professionals and our leading exhibitors.

The negative best suited for enlarging is one that is soft, yet brilliant. But it must be brilliant. The kind of softness that results from full development of an over-exposed plate or film, softness combined with thickness, will not give a good enlargement. Slight fog or veiling of the image is also detrimental, and one must not assume that because such a negative will make a good contact print it should produce a good enlargement. This is a common mistake. The reason for the difference lies in the different action of the light. When the light is projected through such a negative in enlarging, there is a scattering of light from all portions of the silver deposit, and when there is even a slight deposit where it should not be, as in the case of fog or thickness, poor results must follow. In contact printing there is not this scattering of

light and not the same ill effect produced. One should strive for brilliancy with softness, and the use of a lens shade, particularly in the case of our rather short hooded and large aperture anastigmats, will do much in that direction. A safe dark-room light and a clean working developer will also help.

The strength of the light used in making the enlargements also has much to do with the quality of the negative best suited to the workers' requirements. Or rather, one can, by selecting a certain form of light, accommodate the process to negatives of quite different quality. The thin, fully exposed, yet under-developed negatives that some professionals affect, can be made to produce good enlargements only by using a rather weak light, such as an oil burner or gas jet produces. Strong, contrasty negatives require a strong light; and negatives carrying much retouching are best enlarged with well diffused daylight or a strong artificial light, like the arc, with ground glass between it and the condenser. The use of a soft-focus lens is also most advisable in such cases.

The truth of the matter is, the best plan is to find out, by experience, just what kind of negative is best suited to one's individual equipment, and then make negatives as near that standard as possible. It is quite obvious that only a worker with an extensive output to produce could equip himself with apparatus employing varying strengths of light as suggested above. A compromise, to some extent, can be effected by a judicious selection of different grades of paper offered; the range, since the introduction of the so-called chloride papers, with a speed somewhere between that of regular bromide and the gaslight papers, making this power of selection a valuable asset.

I suppose I should attempt to go into some detail on this latter point, but while the range is so wide, it is yet somewhat variable in different localities, and little would be achieved. At least, little compared to what the individual worker can best find out for himself by a very few experiments based upon the quality of the negative in hand and the maker's description of the various papers available in his case.

The exposure is the most troublesome factor of the entire process, but this has lost its terror to a great extent since the advent of developing papers. In the days of printing-out papers, with their visible image to serve as a guide, the correct timing of a bromide enlargement seemed to be much more of an achievement than was actually the case. The best plan, in my estimation, is to take each negative, as made, and give it a number that expresses something in the form of a ratio, something that will give an easily handled factor from which to figure the exposure in enlarging to any size. This can be done by making a correctly timed contact print on developing paper and noting the time, the time serving as the factor number. It is, of course, quite necessary that these factor numbers must all be determined under exactly the same conditions. A standard brand of paper must be used, one having little or no variation in speed, and the light and distance used in making the print must also be uniform.

If all one's negatives bear on their edge the number of seconds exposure required to produce a correctly timed print on, say, Regular Velox, exposed to a cluster of four thirty-two candlepower Mazda lamps at a distance of sixteen inches, little difficulty would be experienced in determining the correct exposure for any one of them for any size of enlargement, after a few experiments had been made. There would be a fixed relationship between these factor numbers and the number of seconds required for enlarging to different sizes, and the relationship could be easily determined by an experiment or two. One might find that the exposure required for a two time enlargement, or enlargement to a certain commonly used size, was one and one-half times the exposure number established by the making of the contact print on developing paper. He then has but to read off the number on the margin of one of his negatives, multiply it by one and one-half, and he has the correct exposure for an enlargement of the designated size, providing that lens stop, strength of light, and grade of paper remain constant. If any of these are varied, proper allowance is easily made. A larger or smaller stop decreases or increases exposure in the same ratio as in regular work; the difference in the speed of the papers used is determined by experiment, and of course one's light is practically constant except where daylight is employed. In this latter case an

actinometer can be used to determine the variation from the normal, if any. Practically all of the annuals carry a table giving the relative exposures for different degrees of enlargement, and I hardly need to occupy space with a repetition of one of them here.

Soft effects in enlargements are sometimes quite desirable, and we know of several firms that are making quite an enviable reputation on their bromide enlarging by using the less pronounced effect secured with the soft-focus lens employed for all their work. But all obtainable sharpness is often desirable, and we must be prepared to secure this last before we can regulate the amount of diffusion to our liking. Some workers find it very difficult to secure a satisfactory degree of sharpness, even from a negative that is undeniably sharp, and we will therefore take up a few of the possible causes for their difficulty. First, there is often an unsuspected lack of accordance between the chemical and the visual image projected by some lights, particularly the enclosed arc. Where this is the case, the variation must be determined by trial and allowance made for it in focussing. While the difference varies slightly with the size of enlargement, only the general difference need be considered and made up except where an unusually large stop is being employed. Where a condenser is used, failure to adjust the position of the light for different sizes of enlargement will also cause lack of sharpness. The light should be so placed that it is in the focus of the condenser for rays of light from the easel; in other words, the cone of light, after passing through the condensers, should come to a point small enough to pass through the stop of the lens. The distance of the light back of the condenser for different positions of the lens, which last means different sizes of enlargement, can be determined by focussing through a negative upon the easel for the desired size, then removing the negative and observing the distribution of the illumination as the position of the light is changed. Another frequently unsuspected cause of unsharpness is the use of the rising and falling, or the cross front, in bringing the image in the desired position on the easel. The centre of the lens, of the negative, the condensers and the light, should all be in a line and not out of centre with each other. It is also obvious that the lens carrying front of the camera or enlarging lantern must be in a plane parallel with that of the other elements, or this centring of the lens cannot be achieved. Dirt on the lens or vibration of some part of the apparatus during exposure is detrimental, and the bromide paper should be perfectly flat against the easel so as to receive the image in the plane of critical sharpness.

Soft effects are, as I have said, frequently the most desirable, both for pictorial and other reasons. A hard, black mass with a sharp outline, is much more objectionable than one with a softer edging, as any landscape worker can testify, if he has given the matter any thought. In portraiture, the breaking up of all suggestion of hard lines is almost sure to result in improvement. With the soft-focus lenses some most pleasing results are secured, and it might be well to point out that different makes of these lenses give somewhat different results. The worker will, if buying a lens of this type, do well to try more than one and decide for himself which best suits his requirements. Bolting silk, stretched on a frame and interposed about three or four inches in front of the paper on the easel during all or a part of the exposure, is a quite common method of securing a breaking up of the image. The distance from the paper regulates the amount of breaking up achieved, and this distance again depends upon the distance of the paper from the lens. A more delicate softening is secured by using two thicknesses of chiffon to face a cap placed on the lens.

In my own practice the mount on the lens is fitted with a wire frame in which a movable slide is held close against the front hood. This slide is a piece of cigar-box wood about three times as long as it is wide, the width being sufficient to well cover the front of the lens. The centre of this slide is left solid, but a circular opening, large enough to permit free passage of light to the lens, is cut in each end. One of these openings is covered with two thicknesses of the chiffon material and the other with a piece of yellow glass, both let into the wood so as to be flush with the surface. With the centre of this slide in front of the lens, the cap is on; with the yellow screen in position, the paper on the easel is in safe light while being adjusted in position; and, with the chiffon section in

front of the lens, my soft enlargements are exposed. One could make the slide longer and include an unscreened opening, but in practice I found that lifting the slide out of the wire frame was less liable to shake the lens than trying to move it along in the proper position.

Even more important control of the results in enlarging can be secured by shading different portions of the image during exposure; or rather, during a portion of the exposure. A piece of cardboard, an old mount, preferably of a dark colour and roughly torn to the desired outline, serves as the shading medium and is to be interposed between the lens and the easel, or at least, some little distance from the paper. This should be kept in motion during the time it is being used, in order to further avoid a too sharp outline, the length of time it is interposed being proportioned to the entire exposure in accordance with the amount of holding back it is thought desirable. It is obvious that where the part to be held back comes fully within the boundaries of negative, this plan will not avail. One can then resort to a piece of the card torn roughly to the desired shape and fastened to the end of a piece of stout wire; an ordinary lady's hatpin answering admirably. Another plan is to attach the shading piece to the centre of a piece of glass and use this last as a support to enable it to be gently moved about so as to shade the part intended. Variations of these suggestions will suggest themselves to the worker and enable him quite rapidly to acquire the knack of exercising most beneficial control of nearly all his enlarging work. In fact, it will be found that practically every negative from which an enlargement is required is amenable to treatment of some kind along this line.

I might point out that availing oneself of these possibilities makes it advisable to increase somewhat the exposure time, and this last is best done by some other means than decreasing the size of the stop. The most practical method is to introduce one or more sheets of ground glass in front of the light employed. Using a slower paper may not give one just the effect desired—different speeds of paper printing differently, and decreasing the stop affects the illumination where a condenser is used and sometimes introduces granularity in other cases, even resulting in an enlarged image of the ground glass diffuser behind the negative being recorded upon the enlargement.

J. WALTER DOUBLEDAY.

PHOTOGRAPHIC RAW PAPER BASE.

THE prospectus of the new company, to bear the title Wiggins, Teape and Co. (1919), which is being formed from the previous well-known firm of paper-makers, Messrs. Wiggins, Teape and Co., Ltd., contains some particulars of the manufacture of raw paper base, which is perhaps the most important raw material employed by makers of photographic papers. It is stated that Messrs. Wiggins, Teape first seriously turned their attention to this branch of manufacture in 1911 when a series of experiments were carried out by the present works chemist at Buckland Mills, near Dover. These experiments were followed by others made at Chafford Mills, near Tunbridge Wells, and in 1914 the Glory Mills of the company at Wooburn Green, Bucks, were adapted to the manufacture of photographic paper base on a commercial scale. It is stated that during the war this plant has been extended from a capacity of 2 tons per week to one of over 20 tons per week, although the mill was at best only a makeshift, adopted during the war, and in many respects unsuitable for the manufacture of this special produce. The company, however, produced a photographic base paper which had been used for certain grades of photographic paper in large quantities with very satisfactory results.

It is now proposed, from the proceeds of the new issue of shares which are offered to the public, to erect a new mill for the manufacture of photographic raw base on land at Wooburn Green at an estimated cost of £300,000. The company estimate that before the war 5,000 tons per annum of photographic raw base were imported into this country from the Continent, chiefly from Germany. The new mill which is to be erected is designed to produce 50 tons per week, or approximately one-half the pre-war imported quantity. Room for further extension is, however, provided on the company's lands, and it is anticipated that makers of photographic papers will make use of this British product rather than resort to

Continental supplies; and it is estimated that a profit of at least 2½d. per pound will be made, amounting to over £58,000 on the estimated output of 2,500 tons. Assuming this to be the case the profit to the company from the manufacture of photographic raw base will be not a very large amount below one-half of the whole profit of the concern. With this large stake in the manufacture of photographic raw base it may be believed that Messrs. Wiggins, Teape will devote the utmost of their experience in the manufacture of the product to maintaining a firm position in the supply of this essential material.

DEATH OF MR. G. WATMOUGH WEBSTER.

It is with very much regret that we announce the death on Saturday last, March 22, from influenza and bronchitis, of Mr. Watmough Webster, at the age of 76.

In his death there passes away one of the few remaining photographers of the old school, men whose practice began within a few years of the discovery of the wet-collodion process, and who lived in

The late G. Watmough Webster.

the days when fortunes in photography were quickly made, and when every new method, such as those which are now the public property of the craft, were jealously guarded by their inventors. Mr. Webster, in some reminiscences published in the "British Journal" not many years ago, recalled how for a long time the production of vignettes and the retouching of negatives were kept closely secret by their originators. Although in business as a photographer, Mr. Webster was his life long an experimenter, more particularly in the working methods which successively came into use. Moreover, he was a fluent writer, and the volumes of the "British Journal" up to within fifteen years ago contain scores of contributions over his name. The subjects of a few, cited at random—viz., studio building, copyright, print-washers, plate-backings, Röntgen rays, the per-sulphate reducer—show the keen interest which he took in the technical side of his craft.

For many years he was established as a photographer at Chester, where he took numerous photographs, some of which were widely published, of Mr. Gladstone and of visitors to Hawarden Castle. There is the story that Gladstone would give his permission for a certain portrait of himself to be taken only if copies could be placed on sale at a price not more than sixpence each. Though knowing the impossibility of complying with the condition, Mr. Webster

signed the agreement, which Gladstone wrote on a sheet of paper, before he would consent to take his place before the camera. On being afterwards proved to him that the distributing trade could not handle the portraits at the stipulated price, the condition was withdrawn. Mr. Webster's last connection with Gladstone was to take photographic copies of his will, written on the pages of a penny memorandum book. Mr. Webster subsequently transferred himself as a photographer to the watering-place of West Kirby, on the Dee estuary, where he continued to be actively engaged in his business to within a few days of his death. An intimate friend of the first proprietor, Henry Greenwood, and the most notable editor, Traill Taylor, of the "British Journal," Mr. Webster's connection with this paper was of a more than ordinarily intimate character. In addition to such signed contributions as we have already mentioned, he was a regular contributor of notes and comments on topics of the hour under the pseudonym of "Free Lance." In the days when Traill Taylor's successor, Mr. Bedding, indulged in a similar habit over the non-de-plume of "Cosmos" there would often be a lively exchange of badinage, interesting chiefly to the two participants and to the inner circle of photographic personages, but more often than not outside the experiences of the non-metropolitan photographer.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

How to Construct a Dark-Room Clock.

A clock to measure the seconds, the face and fingers of which can be plainly seen in the dark room, is a most desirable and useful thing. But one specially made for the purpose at the present time is rather an expensive item. The following instructions will enable any photographer to adapt an ordinary clock at very little cost. Any make or size will do, providing it has a good, bold, white dial and a minute finger, and is one without a pendulum, which will go in any position like a watch. Unless it has a minute finger it will be of no use for our purpose. It does not matter how old the movement is or how defective its time-keeping qualities; these are of no consequence. If we have not one in our possession one can be picked up very cheaply, often for a few pence at a clock repairer's or secondhand store.

Having secured this, we can proceed with the work of convert-

ing it into a dark-room clock. Carefully take the movement out of the case, noticing particularly how it is fixed in, and remove the fingers. Sometimes this latter has to be done before the movement will come out of the case. All screws, washers, fingers, etc., should be put into a saucer or small tray so that they will not get lost, as they will be required later. We should now carefully look at the works and notice just those wheels and spindles which are required to keep the clock going and the minute finger moving. All the rest of the movements are not required by us, and are

better taken out. The best way to take these out without disturbing any other works is to cut through the spindles which carry the wheels with a three-cornered file anywhere where it is convenient. They can then easily be taken out. When all the unnecessary parts have been removed we shall have a clock which, when going, only takes round the minute hand. The dial should now be put back on the clock in such a manner that the centre of the dial where the hour hand was should be fixed over the minute finger movement. This may necessitate a little cutting of the dial, etc., or other parts, to allow it to fit in its right position, but can easily be accomplished. When this is fitted in position the long finger is carefully soldered on to the minute finger and blacked, the minute finger placed in position, and the whole movement put back into the case. We have now a clock which takes just one minute for the finger to go completely round the dial, and each of the hours five seconds. The dial being of a large size and white, and the finger black, it is very easy to see and count the time in the dark room. Of course, the clock will go with once winding as long as ever it did.

It will be seen from the above that there is no provision made for stopping the clock when once it has been wound up until it has run itself down, but it is quite easy to construct an arrangement by which it can be stopped and started at will. To do this it will be well to take a look at the drawing, where it will be seen that a hole is drilled through the top part of the clock, and a knob or turn button fitted in such a way, with washers between, as to carry a piece of bent steel wire that will just turn into the escapement wheel of the clock. This wire should be sufficiently long that when it is turned towards the escapement wheel it will go right through and effectually lock it. When turned back it comes quite clear of it and releases the wheel. This is all worked with the knob at the top, which should not be too easy, but should move nicely. The clock is now complete, and can be wound up and stopped and started at will, and will prove as effective as the most expensive clock specially made for the purpose. That which has been adapted as described, has been in use for six years—E. H.

Exhibitions.

PHOTOGRAPHS BY DR. ATKIN SWAN

The Hampshire House Photographic Society is holding an exhibition of photographs by the President of the Royal Photographic Society, which many will no doubt be interested in visiting, not only out of a personal regard for Dr. Swan's breezy personality, but for the large measure of pictorial and technical quality which the pictures display. The subjects are for the most part presentations of scenes of travel. There are several delightful views of Venice, one of which shows the two well-known effigies of the Crusaders, and another a representation of the Colosseum Statue, which competes with Fremiere's "Joan of Arc" in Paris for the honour of being the finest equestrian figure in the world. A study of the Court of the Lions, in the Alhambra, is another very fine example of Dr. Swan's always admirable technique, and possesses an arresting pictorial quality. But the greater number of the exhibits are Alpine subjects, in every instance of a very high order of technique, and affording a demonstration of the capabilities of the telephoto lens in the hands of a skilled craftsman. The exhibition is open at Hampshire House, Hog Lane, Hammersmith, daily from 2 o'clock to dusk until April 5.

FORTHCOMING EXHIBITIONS.

April 17 to May 22.—Hammersmith Hampshire House Photographic Society Annual Exhibition. Two open classes. Joint secretaries, J. G. Abrahams, 41, Hamilton Terrace, London, N.W.8; A. H. Page, 12, Lime Grove, London, W.12.

Mr. F. Gegg, of Evesham, is carrying out alterations in his studio establishment. The work is being done by Messrs. Epley, of Evesham, from the designs and under the superintendence of Mr. Drinkwater Butt, of 2, Margravine Studios, Baron's Court, London, W.6, whose architectural work for photographers is well known.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, March 10 to 15:—

PRINTING APPARATUS.—No. 6,395. Bromide printer. J. S. Baines and A. A. Pickering.

FILM.—No. 5,926. Photographic film and production thereof. E. S. Balchin.

CAMERAS.—No. 6,159. Lens-adjusting means for folding cameras. A. and R. S. Ballantine J. Lizars, and W. Watson.

CINEMATOGRAPHY.—No. 6,058. Cinematograph camera. A. Barnett.

CINEMATOGRAPHY.—No. 6,471. Shutters for cinematograph projection. W. Bottomley and S. W. Pilling.

CINEMATOGRAPHY.—No. 6,058. Cinematograph camera. E. Esdaile and A. Rose.

CINEMATOGRAPHY.—No. 6,150. Cinematograph machines. M. A. J. Harper and M. E. Myers.

STEREOSCOPIC PROJECTION.—No. 6,313. Means for obtaining stereoscopic effects in projected pictures. G. A. W. Hepburn.

CINEMATOGRAPHY.—No. 6,249. Cinematograph apparatus. T. N. Laws.

PROJECTION LANTERN AND SCREEN.—No. 6,419. Automatic magic lantern and screen. L. P. Linden

CINEMATOGRAPHY.—No. 5,907. Cinematography. C. L. McDonnell.

WORK INDICATOR.—No. 6,381. Photographers' work indicator. G. F. Quilter.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

X-RAY DIRECTORS.—No. 122,780 (June 22, 1918). The director consists of a rod of wood or other suitable material attached to and detachable from any suitable part of the tube-holder, or of a cylinder, or other diaphragm used in combination with a tube-holder. Upon this rod slide two pointers, each pointer having at

Fig. 1.

one end of it a suitable attachment, enabling it to slide backwards and forwards along the whole length of the rod. The rod is arranged in such a way as to enable it to be brought at will exactly parallel to the central beam or X-ray of normal incidence, and at such a distance from that ray as may be found most convenient. The other two ends of the pointers are so arranged as to be when at rest, and to continue to be when sliding along the rod, exactly in the path of the ray of normal incidence. These pointers may be of wood or of other suitable material, and, if made of wood or other material transparent to the rays, may have metal beads fixed in their free

extremities to enable these extremities to be exactly centred with the diaphragm and target of the X-ray tube and to retain this centred position in their excursions along the rod. In Fig. 1 the essential feature of the device consists of the removable arm A pivoted or otherwise detachably connected at C to the X-ray tube box B or other tube carrier. On the arm A are mounted two sliding pointers D, which can be moved to any required distance apart along the arm A. The free extremities of the pointers D may be furnished with metal beads or tips D', so that if maintaining in position a radiographic record of the points of entry and exit of the central beam or X-ray of normal incidence, designated X on the drawings, will be obtained. As shown, the pointers D are applied in this instance one on either side of the head of the patient to be radiographed, and the tips D' coincide with and indicate the path of the central beam or X-ray of normal incidence.

In the alternative construction illustrated by Fig. 2 the director is shown mounted on a carrier attached to the cylindrical diaphragm E, instead of the tube box B. In this case the

Fig. 2.

carrier consists of a metal band F, on which is mounted a sliding or adjustable plate or platform G, capable of being moved to any desired point round the circumference of the cylinder E, and there fixed or clamped in position by a pinching screw or equivalent not shown. The sliding platform G carries a rod or pillar H, upon which is fitted a sliding sleeve or socket I, fixed in position after adjustment by means of a pinching screw J or equivalent device. The arm A with the sliding pointers D, is pivoted or otherwise connected at C to the sleeve or socket I so that the arm can be raised out of the way when desired.

Between the sleeve or socket I and the platform G is a sliding collar L, which can be fixed at any position on the pillar H by a screw M. This collar is adjusted once for all in such a position that when the screw rests on its upper surface the free extremities D' of the pointers are in centre with the X-ray of normal incidence. Its purpose is to ensure that, after temporary detachment and replacement of the sleeve, rod, etc., the free extremities of the pointers shall again come into exact alignment with the X-ray of normal incidence.

Further, the angle of the arm A may be regulated for fine adjustment by the screw K.—George Goring Campion, 264, Oxford Road, Manchester.

DEVELOPING AND DRYING CINEMATOGRAPH FILMS.—No. 123,168 (February 15, 1918). The apparatus comprises a series of tanks, 1, 2, 3, and 4 of any desirable number which contain the solutions through which the film is to be passed for developing, fixing, and washing, and includes also the wringer mechanism for removing the surplus moisture from the film surfaces before the entry of such film into the drying chamber 5, which is divided into compartments by means of hollow perforated partitions connected with a source of supply of air under pressure which is directed against the film for drying the latter preparatory to winding the same upon reels carried by the take-up mechanism.

The mechanism for driving the film through the liquids in the tanks, and through the drier, comprises horizontal shafts 7 disposed near the upper ends of the tanks inclusive, the shafts being journaled in bearings carried by parallel suspension rods 8 secured to the side rails 9 of a frame normally resting upon the upper edges of the side walls of the tanks and adapted to be raised and lowered for withdrawing the suspension rods and

parts carried thereby from the tanks. At their lower ends the suspension rods 8 carry the bearings for the shafts 10 extending parallel to shafts 7. The supports for the bearings of the shafts 7 and 10 also carry the bearings of the vertical shafts 11, each of which is equipped at its lower end with a bevel pinion meshing with a bevel pinion on each of the shafts 10. At their upper ends said shafts 11 carry bevel pinions meshing with bevel pinions on a horizontal shaft extending parallel with the side rails of the frame and journalled in bearings carried thereby. The shafts 7 are idle and each thereof carries a series of idle rolls 17 freely rotatable thereon and with respect to each other. Each of the rolls 17 is bordered by and alternated with discs 18 of larger diameter, the discs being rotatably mounted on the shafts 7 independently of the roller 17.

Each of the shafts 10, on the other hand, carries a series of rollers 19, which are rigid therewith, and are rotated by the shafts, the rollers being separated from each other by the flanges 20 corresponding to the discs 18. The number of rollers on each of the shafts 10 is one less than the number of idle rolls 17, and the rollers are relatively positioned so that the film is trained succes-

Fig. 1.

sively over an idle roll 17, thence over a roll 19, then over to the next succeeding roll 17, and the next succeeding roll 10, and so on from end to end of the shafts 7 and 10 in each tank or in each compartment of the drier. The film passes from a roller 17 in one tank over to a similar roller 17 at the top of the next succeeding tank, but in passing from one tank to the next it is trained over an idle roll 21 loosely mounted on a stud shaft carried at the outer end of an arm 22, which is pivotally mounted on a standard 23. Associated with each of the rolls 21 is a wringer roll 26, preferably covered with chamois skin, loosely mounted on a stud shaft at the end of a freely swinging arm 27, pivotally secured to a projection 28 of the arm 22, the purpose of the rolls 26 being to cause the free liquid carried by the film from each of the tanks through which it successively passes to flow back into the tank instead of being carried over to the next succeeding tank. Thus the carrying of a surplus amount of developing solution into a tank containing a fixing solution or carrying the latter into a tank containing wash water is prevented.

After the film has been passed successively through the solutions in the various tanks, it is trained over an idle roll, with which a wringer roll similar to the rolls 26 is associated, both being covered with chamois skin for causing excess liquid carried by the film to run back into the tank. It is then trained over a further series of rolls for removing free moisture from the film surfaces. It then passes through an opening in one end wall of the drying chamber 5.

The latter contains mechanism which, as shown in Fig. 2, is identical with the mechanism for effecting travel of the film through the several tanks, and comprising shafts 7 and 10 carrying the series of idle and fixed rolls respectively, all of the shafts 10 being, however, driven from a shaft 41 extending horizontally through the drying chamber. In order that the film, in passing through the several compartments of the drying chamber, may be simply subjected to the action of the air currents for drying the same,

there are preferably interposed between the rolls on the shafts 7 and 10 series of idle rolls 42, 43 and 44, whereby the film in travel from a roll on the shaft 7 to a roll on the shaft 10, and vice versa, is brought into close proximity to the perforated walls 45 of the hollow parts 46, by which the drying chamber is divided into

Fig. 2.

compartments. All the hollow spaces in the hollow partition walls 46 communicate with an air chamber 47, which is fed by means of a blower with air under light pressure, and which is preferably filtered, dried, warmed, or otherwise treated for effectually absorbing the moisture from the film during its travel through the drier. The drier really comprises a zig-zag flue (preferably fitted with doors not shown), into which air is continuously forced in one direction, and containing the film which is passed therethrough in a general direction opposite to the travel of the air. Frederick Benjamin Thompson, 1333 Argyle Street, Chicago, U.S.A.

PANORAMIC CAMERAS.—No. 119,032 (September 14, 1917). The invention refers to panoramic cameras having a constant radius of curvature of the sensitive surface in which, by a series of exposures, a panoramic picture extending over 360 degs. without overlapping portions is produced. In such cameras the objective was rotated about a vertical axis during the exposures. This requires complicated mechanism, and has the disadvantage that the picture loses in sharpness by the rotation of the objective. Where the light passes through slits to the objective, and from there to the sensitive surface, the strength of the light is considerably reduced.

The invention has for its object to avoid the above-mentioned disadvantages and to provide a simplification of the camera and the production of sharper pictures. This result is obtained by projecting the picture with the objective stationary on a stationary sensitive surface forming part of a cylinder.

In the drawings 1 is the body of the camera for taking panoramic pictures on film. The outer surface, 2, of the rear wall, 3, of the camera, 1, is curved to the radius of the focal distance, 4.

On this cylindrically curved surface lies the part of the film, 8, on which the particular picture of the series is being taken.

In taking each picture the objective, the centre of which is denoted by 5, as also the part of the film on the partly cylindrical surface, 2, of the camera, 1, remain at rest, so that a very sharp picture is taken. The complicated mechanism previously required for rotating the camera and feeding the film during the exposure are dispensed with, so that the panorama camera can be inexpensively produced. Nicola Stefani, Calprino, Tessin.

New Apparatus, &c.

The Ensign Printing Machine. Made by Houghtons, Limited, 88-89, High Holborn, London, W.C.1.

A piece of apparatus for the professional photographer just being introduced by Messrs Houghtons is deserving of prominent notice not only upon its merits, which are great, but from the fact that

it is the first new introduction in the way of photographic apparatus which has reached our table since the conclusion of hostilities. As shown in the illustrations the printer is designed to stand on the floor of the photographer's workroom, its top coming to the comfortable height of 31 inches. It is designed for taking negatives of all sizes from 15 by 12 inches. Those of the latter size are laid within the rebate which holds the plate-glass bed; carriers are provided for smaller sizes, the negatives being thus placed centrally in the machine. Lamps are not provided with the machine, so that the user can, in fitting them, please himself as to

the power which he shall choose, and may thus reduce the length of exposure when employing the slower papers.

The apparatus is fitted with a sheet of ground glass immediately below the bed, and below that again a very convenient pattern of vignetter. This consists of a metal plate with a relatively large central aperture, pivoted around which are a number of thin metal plates with serrated edges. By bringing these plates into position—they are sufficiently stiffly mounted to stay where they are put—a vignetting aperture of any required size and of almost any shape in common use can be created in a few seconds. The vignetting plate is instantly removed from the apparatus when solid prints are to be made, and the same remark applies to the ground glass which the photographer may be glad to dispense with in the case of

negatives of exceptional density. The pressure board is made in two hinged portions and is operated by a handle which, if required, automatically locks itself in the position of pressure and thus relieves the user of the machine from the necessity of keeping down the handle himself. On the other hand if exposure is only of a second or two's duration the automatic latch is readily put out of action.

The whole apparatus is most solidly and substantially made and the practical convenience of the user is consulted by providing two hinged flaps on either side which usefully serve for holding supplies of paper and of exposed sheets or of keeping negatives at hand for use. The price of the machine, complete with carriers for negatives from 12 by 10 down to $\frac{1}{4}$ -plate, ground-glass diffusing screen and vignetter, but not including the electric lamps, is £12 12s. 0d.

MESSRS. WELLINGTON AND WARD ask us to make mention of a packet which has reached them in one of their plate boxes containing a miniature of a lady and a postcard size negative of a family group. The address label has become detached, and it is hoped that the insertion of this notice may meet the eye of the owner, probably a miniature painter, who may obtain his property on communicating with Messrs. Wellington and Ward, at Elstree, Herts.

Analecta.

Extracts from our weekly and monthly contemporaries.

The Oil Transfer Process.

I WOULD recommend (says H. Hertram Cox in the "Amateur Photographer and Photography" for March 26) for the first inking up a paper which, being expressly made for transfer, possesses extraordinary advantages. I was led to use it by a reference in Vol. 31 of the "Amateur Photographers' Library." It is called "Autotype litho transfer paper," and has a very glossy surface. It is therefore not very suitable for the ordinary oil process, but possesses peculiar advantages when transfer is the final result desired. It can be procured from the Autotype Company. The roll is best sawn through so as to make small rolls of the width required by the user. Lengths can then be readily cut off as and when required. A 5 per cent. bath of potassium bichromate, with or without the addition of a few drops of ammonia, should be employed. The sensitised sheet prints very quickly, and should be printed well out; the details in the highlights should be clearly distinguishable. When finished, the print should at once be cut to the size of the finished picture, leaving no margin, and plunged into tepid water. The temperature of the water is important. It should not exceed 75 degs. F., and 72 degs. is safer. The water should be changed every five minutes or so until the bichromate is completely washed out. When this has been accomplished, further soaking will, in most cases, be seen to be entirely unnecessary. The image will stand out in strong relief—the greater the exposure the stronger the relief—but it is unwise to press the exposure too far, or familiar difficulties may arise later in the course of inking up.

CATALOGUES AND TRADE NOTICES.

MESSRS. J. H. DALLMEYER, LTD., send us a list, just issued, of their cinematograph taking and projecting lenses, those of the former class including a telephoto series on the model of the Adon, in which the focal length is double the camera extension. The projecting lenses are made in focal lengths from 2 to 7 inches, and of aperture from $f/2$ to $f/5$.

MR. ROBERT BALLANTINE, 99, St. Vincent Street, Glasgow, has just issued a 24-page list of high-class second-hand apparatus. It includes only goods of established reputation, such as Umo, Sibyl, and Vesta hand cameras, Sanderson field cameras, Soho and Graflex reflexes, Ensign and Kodak film cameras, and lenses by the best makers. The list is sent on request.

Commercial & Legal Intelligence.

LEGAL NOTICES.—Charles Frederick Michell, photographer, 121, High Road, Balham, has been adjudicated bankrupt. The receiving order was made on the debtor's petition.

Notice is given of the dissolution of the partnership between William Edward Paradise and Elias Goldsmith, carrying on business as photographers at 2, Bute Place, Cardiff, under the style of Paradise and Goldsmith. All debts due to and owing by the late firm will be received and paid by William Edward Paradise.

SPECIALTY TRADE WORK.—A frequent contributor to our pages, Mr. D. Charles, who has lately been demobilised from official photographic work in the Royal Engineers, has just started in business for himself at 363, Garratt Lane, London, S.W.18, as a maker of postcards and postcard enlargements from professional photographers' and amateurs' negatives, and in the production of other specialties of which we shall have something to say on another occasion. A special feature of postcards made by contact from photographers' negatives is the insertion of an attractive border and imprint which, as we see from a specimen sent to us, adds a very finished appearance to the card. Mr. Charles is also making a specialty of preparing copy negatives on thick, flat film, and offers his services in the production of line and panchromatic work of this kind to any special requirements. He is also a specialist in blocking out, inserting backgrounds, and other "fake" work of any description. Knowing him to be an expert worker in the branches which he offers to undertake, we have no doubt that there are many photographers who will be anxious to avail themselves of his services.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, MARCH 29.

Huddersfield Naturalist and Photographic Society. "Notes on Flat Fishes." F. W. Mills, F.L.S., F.R.M.S.

MONDAY, MARCH 31.

South London Photographic Society. Portfolio Exhibition, arranged by W. E. White.

TUESDAY, APRIL 1.

Royal Photographic Society. "Commercial Photo-copying Processes." S. Bakeroff.

Chelsea Photographic Society. Dark Room.

Manchester Amateur Photographic Society. "Clouds in Prints and Slides." W. W. F. Pullen.

WEDNESDAY, APRIL 2.

Croydon Camera Club. "Home Portraiture." W. Foster Brigham.

Dorsetshire Amateur Photographic Association. "Amateur Photographer," and "Photography" Prize Slide.

Edinburgh Photographic Society. "Architectural Photography." W. C. G. Collins.

Tuobridge Wells Amateur Photographic Association. "Tramps in Tyrol." G. W. Perkins.

THURSDAY, APRIL 3.

Hackney Photographic Society. "Round the Mediterranean." Dr. C. Atkin.

Huddersfield Naturalist and Photographic Society. Lectures by C. Wood, J. H. Carter, W. H. Houghton, and F. Hain-liffe.

Birmingham Photographic Art Club. "Stories of Dartmoor." F. W. Pidditch.

Richmond Camera Club. "An Explanation of Some Photographs of Fire Brigade Work." S. G. Hamble.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, March 25, Mr. E. W. Mellor in the chair.

Mr. R. H. Goodall, late Lieut. R.A., delivered a lecture on "Egypt—Its Antiquities and People," illustrated by a large number of lantern slides. Mr. Goodall showed his audience photographs of the ancient temples and tombs of Egypt, and had some theories of his own on the evolution of distinctive types of architecture. The later portion of his discourse on the places and people of modern Egypt was of equal interest.

On the proposition of the Chairman, the very hearty thanks of the meeting were accorded to the lecturer.

CROYDON CAMERA CLUB

"But I cannot think of a subject," nervously expostulated Mr. J. Walker, when firmly commanded to make a first contribution to the syllabus, and knowing Mr. Walker, the title of last week's paper was instantly supplied, namely:—"The Defects and Imperfections of Photographic Apparatus and Materials," which, after brief cogitation, was accepted.

A popular member for many years he has been an acquisition to the club, a distinct personality giving him a niche of his own. In photographic pursuits he presents himself as a martyr to unfortunate coincidences. If not narrating actual experiences, by way of illustrative remarks, it may be said that if one out of many anastigmats has a bad bubble, that lens is sure to be sent him by the makers, and equally certain is it that the bubble will be right in the centre of the glass rendering $f/64$ imperative. Mr. Walker never uses this stop, but this does not alleviate his harrowed feelings. Again, if perchance isolated defects occur whilst dry plates are being made, when cut to size all the damaged goods in some mysterious way will find themselves in one plate-box neatly addressed to "Walker, Croydon." This is resented and leads to a material increase in the receipts of the Inland Revenue through its postal department.

If troubles do not arise with normal frequency, things seem a bit dull and "unwalkerisk," so out he starts on a voyage of discovery. Whilst punting about the other day pining for fresh indignities, a veritable outrage was dropped upon by his unearthing a statement made by the manufacturers of an exposure-meter to the effect that the sensitive meter-paper had considerable orthochromatic properties. Now, Mr. Walker uses a meter and often ordinary plates, and the fat was in the fire indeed, for if the meter

paper indicates correctly for orthochromatic plates, what price the poor "ordinaries"! Left out in the blooming blue cold, so to speak. A brisk encounter between the indignant amateur and two concerns implicated followed.

As a matter of fact the point only arises in reference to evening light, text books telling us that orthochromatic plates are relatively faster than ordinary plates to the mellow light of departing day, which is quite right and proper, as any suggestion to the contrary would perplex the student. Possibly some day someone competent to do so will make a few definite experiments to ascertain if any appreciable difference does exist in general landscape work under ordinary conditions. With an orthochromatic plate behind a filter obviously the horse is of another colour.

As to the lecturer's paper nothing but praise can be given; it dealt with a most varied assortment of cameras and accessories which had passed in long procession through his mechanical hands, and all about to camerise would not do better than consult Walker. A very useful member to have in a club. Most which he had to say was of real value, being based on experience and keen examination, but an epitome would be in the nature of a Hampton Court maze with an action for libel threatened at every wrong turning. On the other hand, when praise was due it was given, but good points are never so obtruding as bad. We also refrain from describing his ingenious specification for a perfect camera, including almost every movement and many novel adjustments, all compressed into a folding reflex, as the suggested "better 'ole" is in the region of Colney Hatch for camera designers.

An experience with a stereo-camera fitted with paired anastigmats and largely used with orthochromatic plates and two cap light-filters, deserves mention to emphasise one old point. The camera was received just prior to starting on a holiday on the Continent. On return, with his usual luck, in many cases the pictures on the left were found to be fuzzy, and those on the right dead sharp, whilst in others this state of affairs was reversed. The respective makers of camera and lenses then experienced an interesting time, the camera being suspected of variable parallelism, the lenses of being unhappily mated, but they failed to throw any light on the trouble, which was eventually traced by the lecturer to one of the light-filters acting as a weak supplementary lens, varying the focus of the objective on which it happened to be placed.

And so the account of "Walkerisms" went distressingly on until towards the end when the sun broke through the clouds, one envelope system of changing plates receiving his warmest recommendation having never been known to break down. In showing the working of a model a finishing touch was added to an altogether excellent evening by the apparatus sticking in the most obstinate fashion. "Deuce! if I know what is the matter with it," sadly said Mr. Walker.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—At the last meeting Mr. N. F. Horne, F.R.P.S., delivered an interesting lecture on Practical Intensification and Reduction, which the lecturer described as the repairs department of photography, an essential department, in which the beginner had too much faith and the more experienced worker not sufficient. While admitting it is preferable to be able to produce a perfect negative as the result of each exposure, conditions sometimes militated against such perfection, and while after-treatment would make the best of a bad job, the worker must educate himself to recognise whether or no intensification or reduction was necessary just as soon as the negative leaves the fixing bath, as a negative at this period is better to work upon than one which has been allowed to dry. If, however, the negative is dried before either intensification or reduction the drying acts as a handicap.

A dried negative may show no signs of finger marks upon the film, but there is no evidence to prove that none exist; hence the film, for greater safety should be cleaned with benzine or petrol and then soaked in a weak solution of hydrochloric acid 1 in 60 for from 5 to 10 minutes; afterwards the negative should be subjected to prolonged soaking in plain water, not less than 30 minutes, while 3 hours would be better. Chromium intensifier is the most satisfactory, as greater or less intensification could be obtained by the

varying the strength of the intensifier, moreover the whole operation can be carried out in weak daylight or artificial light. A stock solution of potass bichromate 1 oz., hydrochloric acid 80 mins., water 10 ozs. is quite a reliable one. For use, take one drm. of stock solution and add one oz. water; this provides the maximum intensification, and the operation can, if necessary, be repeated. For re-development a clean working developer such as amidol should be used, in fact the only developer not suitable is pyro.

Strange though it may seem, a stronger solution provides less intensification. The bleached negative must be washed until all the yellow stain is removed. If less intensification is required take 2 drms. of stock solution to 1 oz. water and add 5 mins. hydrochloric acid. For soft effects the bleached negative can be printed from without the subsequent re-development of the image, and good results obtained.

Tabloid mercuric iodide was recommended, but unfortunately, the lecturer remarked, it is not under control like chromium; nevertheless good results can be obtained provided care is taken to keep the dish on the move, and a good clean result will be ensured if the surface of the negative is carefully wiped after the intensification is completed. This intensifier increases the density in proportion. Uranium has one distinct advantage in that, should the intensified negative be unsatisfactory, the action of the intensifier can be removed by the application of weak ammonia, and the operation recommenced. A dry negative can be partially intensified, action only taking place in the shadows, or clear portions, before the high lights are touched: this is often a great advantage where under-exposure and over-development are concerned.

Unquestionably the most popular and useful reducer is ferricyanide and hypo. Rinse the former under the tap before use, and have everything ready to hand before mixing up the solution—the exact proportions are not a matter of great importance, but a clean and fresh solution of hypo is essential if stains are to be avoided.

For even reduction use a weak solution: local reduction can be carried out by the use of cotton wool plus reducer, but the cotton wool must not be kept in use for a long period, and it is always advisable to keep near the tap. In no circumstances should a negative be taken direct from the fixing bath and placed in the reducer, as a good wash is necessary to remove the dissolved silver from the negative. Another very useful method is to bleach the negative in a sulphide toning bleacher, wash for 20 minutes, and re-develop with amidol for a portion of the time usually given for the developer to have complete action.

This will strengthen the shadows and stop short in the high-lights. The negative should then be fixed in a clean hypo bath and washed.

Correspondence.

. Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

. We do not undertake responsibility for the opinions expressed by our correspondents.

ARE MATERIALS PRICES TO FALL SOON?

To the Editors.

Gentlemen,—On page 54 of the "B.J.," dated January 31 last, you published a letter of mine forecasting an early reduction in the price of dry plates because of the withdrawing of certain Government contracts and the disappearance of certain names from the official list of contractors in the "Labour Gazette." In the following issue of the "B.J.," pages 62-3, Mr. Harry Hunt took me to task for airing such views, as also did the "Photographic Dealer."

Anyway I learn from the current issue of the "B.J." (page 149) that the price of dry plates were reduced on March 11, so that my prophecy has turned out to be correct.

I am now writing to ask you to tell my professional brethren to be of good cheer, for the current issue of the "Labour Gazette" has just arrived, and again the names of photographic manufacturers are conspicuous by their absence. We may, therefore, expect another reduction in price very soon. This, however, will be the last letter

that I shall send to you on the subject, as I do not wish to get into the habit of pointing out the accuracy of my forecasts.—Yours faithfully,
H. GREEN.

THE ASSISTANT QUESTION.

To the Editors.

Gentlemen,—As a photographer of some fifteen years' standing, and having just been demobilised after four and a-half years of Army life, I am much surprised to read the letter by "Simple Simon" in to-day's issue. Has the profession really fallen to such a degraded state as "S.S." says? Apparently there are no photographic artists left. All styling themselves as such must be either (a) a pure profiteer with no personal knowledge of his art, (b) a rogue and humbug, or (c) a pettifogger and producer of glorified cardboard. Has "S.S." never met the man (and there are many such) who really loves his work, and to whom the art of producing a portrait (in the full and true sense of the term) is a constant joy? The work of these men must on its own merits come to the fore and, from a commercial standpoint, "sell." These men will only employ the best assistants they can get, and will pay them the best wages in the same way that they invariably use and pay the price of the best material.

Poor "Simple Simon!" his knowledge of photographers is indeed limited, or perhaps his own special bits of glorified cardboard do not compare favourably with some of the West-End piffle, and the public as a whole is not a bad judge.—Yours very sincerely,

High Street, Eastleigh. FRANK CHIVERS.

THE EFFICIENCY OF THE FOCAL-PLANE SHUTTER.

To the Editors.

Gentlemen.—In the article of a fortnight ago about focal-plane shutters you gave extracts from Colonel Moessard, 1901, and also from the "Photo-Miniature," 1916. With regard to the former, you print a diagram in which he gives reasons for estimating efficiency on the ratio of E.G. to E.H. He says that the covering and uncovering of E.F. and G.H. are equal and opposite in order, and therefore can be reckoned as half the time. If we are to accept the usual definition for defining shutter efficiency, we can hardly cut off arbitrarily some of the time that is occupied in opening and closing, but, apart from that, this diagram is obviously and hopelessly wrong. There is only one way in which the plate could be illuminated as sketched, and that is by converting the lens from the refractor it is designed as into a circle of illuminated ground-glass, which it emphatically ought not to be.

The path of the rays from any point of light is "parallel" until the lens is reached, and then it converges to a point on the plate in the form of a cone, and the image is, after all, only made up of a number or aggregation of such points.

If you use a slit of $\frac{1}{2}$ at a distance $\frac{1}{2}$, the cone of rays that will just pass without eclipse will be obviously from a lens of $f/3$; reduce the aperture to $f/4.5$, and the diameter of the cone of rays will be reduced to $\frac{2}{3}$, or $f/6$ to $\frac{1}{2}$, and $f/9$ to $\frac{1}{3}$ of the slit width.

The second part of the article, from the "Photo-Miniature," grasps this point all right (though it does not appeal to me as being very clearly put), and really damns the previous diagram in the same contribution; though, curiously enough, here, too, they take the successive times of opening and closing, and then put them down as half their value. It may be all right, but in any shutter efficiency data with diaphragm shutters the opening and closing are always taken for their full time value, so why not focal-planes?

But, anyhow, that No. 1 diagram should never appear again in any connection with discussions of focal-plane efficiency.

CHAS. S. DYER.

Myrtle Cottage, Chase Road, Southgate, N.

[The writer of the article replies:—"Your correspondent is apparently led to dispute Moessard's representation by the fact that in the case of each of the four pencils of rays only one limiting line is shown. If your correspondent completes the diagram, he will see that it is identical with that from the 'Photo-Miniature.' The expression of two phase-periods of 50 per cent. efficiency as a single half-period of full efficiency seems to me a convenient method for obtaining the ratio of full to partial exposure."]

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

J. W. PARKER.—If you mean wooden dishes, the best thing is to iron in paraffin wax.

M. GOLDSMID.—The Roland E. Green Manufacturing Company, Hastings, Mich., U.S.A. The price is \$15.50.

A. F.—A quick retoucher could do six such heads per hour, but in most cases three or four per hour would be the average output.

A. S.—We do not know the makers of the lens you describe, but if it is in good condition and average quality it should be worth from 15s. to 25s.

J. P.—The lens is apparently a portrait combination, and probably of fair quality. It is of little value now, being worth perhaps from £2 to £2 10s.

INTERNATIONAL.—You can get a by-pass tap from any dealer in laboratory appliances, such as Messrs. Phillip Harris and Co., Edmund Street, Birmingham.

B. B.—A licence is still necessary. As mentioned in the "B.J." of March 21, you need to apply to the Secretary, New Business Licenses, 82, Westbourne Terrace, Paddington.

JAMES.—So far as we know the Hansa printing machine, made by Messrs. Houghtons, is the only one in which a foot treadle is used for the application of the pressure back.

J. S. A.—None on emulsion making which are not twenty years old and out of date. The best general book is "The Science and Practice of Photography," by Chapman Jones.

RED PAINT.—They are all very old lenses, and none of them would fetch more than a pound in the market. If you have use for them, we should say you had far better keep them.

H. C.—The dyes which we had in mind when replying to our correspondent are those sold by Mr. A. V. Godbold, 98, St. Asaph Road, Brockley, S.E., which we have reason to think are as permanent as any you can get.

E. F. C.—We do not give formulæ, as the preparation is so dangerous, and we advise you not to attempt. If you must, one of the best formulæ is to mix the magnesium powder with an equal weight of potassium nitrate.

CLACKCANNON.—No, professional men are not exempt. The best advice we can give you is to get hold of the clerk of the court and endeavour to get called as soon as possible. As we know to our cost, most of the delay is taken up by waiting to serve.

J. E. (Vancouver).—The only French photographic paper at present published is the "Photo-Revue," 118, Rue d'Assas, Paris, VI. If you mean portraits of stage celebrities, the largest firm of publishers here is the Rotary Photographic Company, West Drayton, Middlesex, who issue a very large series of postcard portraits.

SHANSI.—We should say the adhesive could be used with safety for developed prints, but it is usually slightly acid and ought not to be employed for P.O.P.'s. In any case, we cannot see any advantage in using it in preference to a good dextrine paste, which is just as adhesive and infinitely cleaner and more convenient in use.

DEVONSHIRE.—Soft washing water certainly makes a difference, and is probably the cause of the blisters. The prints should be passed through a hardening bath of formaline or alum before being toned, or it would probably answer as well to fix them in a fixing-hardening bath of hypo, alum, sulphite, and acid, made up according to the customary formula.

R. A.—The printing of silk sensitised by floating on a silver bath is usually done by attaching the silk with a touch of fish glue to a sheet of stiff paper so as to permit of examination during printing. The silk requires to be printed considerably beyond the depth required in the finished print, and is toned in a bath of gold, and acetate as formerly used with albumenised paper.

BRIENSIS.—There is very good ground for your customer's objection. Surely it should be generally known by this time that the customer has the right to prevent his or her portrait being exhibited in the photographer's showcase. The best thing you can do is to admit that the letter was written under a misapprehension, and remove the portraits as you are asked to do.

GRANDISON.—The prints have all the appearance of not having been properly fixed. As we have said many times, prints should be passed through two fixing baths in succession, renewing the first as soon as it is becoming exhausted. The best test for the activity of a fixing bath is to immerse a slip of dry-plate in it and notice the speed with which the white emulsion is dissolved away. If it takes longer than five minutes for the slip to clear, the fixing bath may be taken as exhausted for fixing prints.

A. M.—Albumen prepared from blood can be bought from any dealer in chemicals, such as Messrs. Johnsons, 23, Cross Street, Finsbury, E.C. It is still necessary to obtain a licence in order to start a new retail business of whatever kind. But we should say that it is now merely a matter of form, and you will have no difficulty in getting it from the branch of the Ministry of Labour which deals with the matter and has its address at 84, Westbourne Terrace, Paddington, W.2.

T. S. L.—It is a mistake, but one which is found often repeated in photographic text-books. You had far better have the dark-room papered a light yellow or orange. If black scarcely any reflected light is diffused into the room, and it becomes very difficult to find anything which does not happen to be in a direct line with the dark-room lamp. The advice probably dates from the days when photographers were badly provided with glass for dark-room illumination; but with the present safelights there is no object whatever in having the walls a dark colour.

A. G. B.—Unless your builder is a skilled portrait photographer it is useless to listen to his ideas. There may be plenty of light, but if it is not in the right place you will not get good effects. Putting in the small skylight would only be a waste of money. So far as the appearance of the roof goes, it is for you to decide whether you prefer a pretty studio to good work. The object of widening the top light is to enable you to make up for the deficiency of side light by using it a more oblique angle. The studio we mentioned is in London, but we do not think the occupant, a lady, would care to show it.

F. S.—It is not so much a question of how many feet of glass is needed for the studio as the position it occupies. We should recommend four feet top and side at each end to be solid, the side light beginning at three and a-half feet from the floor up to the eaves; this will be twelve feet long. The roof should have glass halfway up the slope and be the same length as the side light. Good horticultural glass (sheet) will do very well, but if you want to prevent people looking through you should use rolled plate. This costs a little more, but it is stronger. It is much used for studio glazing.

G. W. K.—It is impossible, or, at any rate, very difficult, to get a good negative of a line subject on a rapid portrait plate. You should use a process or photo-mechanical plate, and develop preferably with hydroquinone. This will give you a negative with a very opaque ground and very nearly glass clearness in the lines. Very often there is an advantage in over-developing and then clearing the lines by going over the plate with Farmer's reducer applied on a tuft of cotton wool. This is better than immersing the plate in the reducer, as it removes superficial fog without the same degree of action on the general deposit.

A. S. II.—We cannot identify your old lens, but what you want is done very satisfactorily with a short-focus lens of large aperture, such as the Aldis photo-micrographic lens of 3-in. focal length; price (pre-war), £1 10s. 6d.; or with the *f*/6 Aldis of 4½-in. focal length, similarly priced. With the former lens, assuming that you have a camera extension of 20 ins., you can enlarge to nearly six diameters. If you do not want to enlarge to such a large scale as this we should advise the 4½-in. lens, on account of its greater covering power. Messrs. Houghtons or Messrs. Butcher supply double plate-holders, but it would be necessary to have an adapter made to fit into the existing groove of the Pressman reflex—that is to say, if you wish to use them alternately with the metal slides.

SHOP STUDIO.—I have a portable studio here, but should like to use shop, if possible, to do away with present studio. The one big drawback to this shop front is that the sun is on all the day, very strong in the summer. Do you think that by stippling the windows with white and the use of white and green case-ment curtains I could overcome this? Also, do you think the lighting arrangement would be satisfactory for busts, full-length figures, and small groups of three or four figures?—R. C.

We think you will be able to control the light in the way you suggest and get good results with single figures. You will have a little difficulty in getting groups evenly lighted, but you should be able to manage. If you have electric current a couple of half-watts would be a great help in giving a top and front light.

F. J. I.—We are afraid you will find a half-plate reflex too bulky and weighty a camera for outdoor work. Although more skill is needed in judging distances, you had much better choose one of the folding focal-plane cameras of the Goerz Anschutz type. 2. You have so much length in your studio that you can use a lens of almost any reasonable focal length. We think you had much better choose a 3B than a 2B Dallmeyer. It is the best all-round lens for studio portraiture, and practically as useful in 99 per cent. of the ordinary work as the 4B, which costs exactly double. For groups you cannot do better than get an anastigmat lens of about *f*/6 aperture. As we do not know what size of plate you intend to use of groups, it is impossible to advise you as to the focal length, but if you mention the size of the plate and the over-all width of the group in the studio any of the lens makers would tell you which is the requisite focal length.

SUMMARY.

Mr. D. Charles has originated a new intensifying process: one suitable for line negatives and giving very great density of deposit, with good clearness in the lines. The negative, bleached as for chromium intensification, is subsequently treated with mercuric iodide and with sulphide. (P. 172.)

In a leading article we deal with the qualities of photographic printing processes in reference to the preparation of prints which are to be preserved as records. It is pointed out that the fact of bromide or silver prints having lasted in good condition for a fair number of years is not a sufficient basis on which to recommend their use in the making of record collections. The platinum and carbon processes are, however, on a different footing in this respect. (P. 170.)

In this week's article "Practicus" deals with the equipment for home portraiture and with the considerations, as regards lighting, which require to govern the making of portraits in "atter's homes." (P. 172.)

In a contributed article Mr. George F. Burrell has some advice to give on the practice which is advisedly followed in the training of retouchers. (P. 174.)

At the annual general meeting Mr. H. A. St. George was elected president of the Professional Photographers' Association and a resolution carried to raise the annual subscription to ten shillings. (P. 175.)

A convenient form of dark room sink is described by a Paris correspondent. (P. 175.)

Used for papers which it suits, the method of toning with "liver" of sulphur can provide a speedy and very effective substitute for the customary process of bleaching and sulphiding. (P. 169.)

Those who complain of lack of density in negatives on ultra rapid plates should revise their ideas of development. Thinness is invariably due to under-development—that is to say, for an insufficient time or with an improperly compounded developer. (P. 169.)

An imaginary obstacle to the use of the carbon process is veiling of the tissue from gas fumes, etc. While all possible exclusion of such fumes requires to be made when drying sensitised tissue, the dry tissue, such as can be brought ready sensitised, is remarkably unsusceptible to fog from this cause. (P. 170.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT

A patent of Mr. Aron Hamburger's relates to a process for making a two-colour cinema film by simultaneously impressing the two monochrome images upon opposite sides of the film band. (P. 13.)

Details of the method of Mr. S. H. Williams by which Bromoil enlargements from a single three-colour banded negative are made are quoted from the "Journal of the Royal Photographic Society." (P. 15.)

EX CATHEDRA.

Liver Toning.

There seems to be in some quarters a difficulty in getting satisfactory tones on bromide prints with the ordinary sulphide toning process. Instead of obtaining good rich sepia tones a rusty colour is got, due sometimes to a want of density in the negatives, or to over-exposure followed by insufficient development, while in other cases no modification in working will give the desired colour. To those who find themselves troubled in this way we recommend a trial of liver of sulphur (potassa sulphurata) as a toning agent. This has the advantage of giving a variety of colours, ranging from a warm black to sepia, including some very fine purple browns. One of its good points is an absence of the slight reducing tendency of the ferricyanide bleacher, and another is that even if the prints are inclined to be weak there is no liability to give a "ginger" colour. The process is a simple one; the toning bath consists only of sixty grains of "liver" to a pint of warm water, a few drops of ammonia being added when solution is complete. This should be raised to a temperature of about 100 deg. Fahr., and the print immersed until the desired colour is reached. A little allowance must be made for the further toning action, which goes on in the subsequent washing. Some papers will stand the heat of the solution without requiring hardening, but if there is any tendency to melt the prints should receive a preliminary bath of formalin, a convenient strength being two ounces to the pint. As with the hypo-alum bath, all papers will not tone to sepia in the liver of sulphur solution, some refusing to go beyond a purple black similar to P.O.P. A few trials with various papers will show the most suitable makes.

Rapid Plates

It is commonly believed that it is difficult to obtain full density when using very rapid plates, and some operators prefer to use a slower grade in order to secure plucky negatives. The idea is fostered by the fact that the films of nearly all fast plates appear much more transparent before development than do those of slower ones, and this gives rise to the belief that such plates are thinly coated and lacking in silver. Such is certainly not the case, the fast plates having in some cases twice as much silver bromide spread over the square inch as the "ordinary" ones. We have used plates which were so transparent that ordinary printing could easily be read through the emulsion, but which gave almost perfect opacity when developed. The fact is that much longer development is necessary for a fast emulsion than for a slow one. If we take two plates of the same make, one an ordinary and the other a "super-sensitive," expose both correctly and develop in the same developer for the same length of time, the difference will

be most marked, but if the rapid plate be developed twice or even three times as long the densities will then be pretty even. Instead of prolonging the development the same effect may be produced by increasing the amount of alkali, or by raising the temperature of the developer. With regard to the former expedient, a little mishap which recently occurred to us will be instructive. By mistake carbonate of soda was used instead of sulphite in making a stock pyro solution, and by so doing the amount of alkali in the mixed developer was more than doubled. Upon developing for the usual time plates which normally gave thin delicate images became so dense that considerable reduction was necessary before the negatives were printable, a conclusive proof that a full quantity of silver was present.

Carbon Print- In some unaccountable way the notion **Ing and Fumes.** has been created that carbon tissue is extremely sensitive to various fumes, and many have been deterred from using this charming process because they thought that special precautions had to be taken to avoid "tinting," or what would be called "fog" in other processes. We have recently seen excellent carbon prints, which were produced day after day under conditions which are popularly believed to be impossible. They were made in a work-room in which an evil-smelling dry-mounting press was used almost constantly; by the side of the sink a geyser was used to supply the hot water needed, and three feet away the sulphiding of bromide prints was constantly done. The reason for the immunity from the ill effects of this combination was a simple one; only ready-sensitised tissue was used. In a dry state the fumes had practically no effect upon it, and the short time it was exposed while wet during the mounting did not allow any action either. The great stumbling-block in carbon work is the drying when home-sensitised tissue is used, and practically all risk of "tint" may be avoided by drying the tissue in an air-tight box or cupboard over chloride of calcium. By so doing, not only is the atmosphere excluded, but the drying is done in the same time whatever the hygroscopic conditions may be outside. Another advantage gained by this method of drying is that the tissue is of uniform sensitiveness, which is not the case when it is dried in the open.

Semper Paratus. There is an old joke which is sometimes trotted out when anything uncommon presents itself "that you always see these things when you have not got your gun." If for gun we substitute camera we are recording the experience of nearly every photographer. Most of us can recall many occasions when we have seen effects of light and shade, or occurrences, which are not likely to be repeated, and have been compelled to leave them unrecorded because our camera was out of reach. We have known some photographers, mostly enthusiastic amateurs, who never went out without a camera, and at least one professional who did the same, and he told us that, on the whole, the practice had been a profitable one, besides being the means of securing many pictures of personal interest. This was in the days when the smallest camera was of the dimensions of a cigar box, and it required much more enthusiasm than in these times of pocket Kodaks and "baby" plate cameras. Apart from the constant carrying of a camera, it is an excellent plan to keep a small instrument, say, half-plate or less, ready filled with plates or films which can be picked up and used without a moment's delay. In this respect the amateur with his film outfit is usually much better prepared than his professional brother, who often has to assemble his outfit before it is ready for use. Perhaps

the most convenient apparatus is of the folding focal-plane or "press" type, in which plates can be kept for weeks without danger of deterioration. Such a camera is of great value for sports, pictures, street scenes, and the like, while used with discretion it is very handy for home portraiture. The great point is that it should be *semper paratus*, always prepared.

For Print-Out Papers. The consistent reader of the photographic papers is constantly coming upon hints so ancient that, like the anecdotes of Miss Volumnia Deadlock, they have become in the cycles of time new again. At least forty years ago photographers who had need to make a very dense part of a negative impress its detail fully on the print would use for the purpose the concentrated light of a burning-glass. This old expedient must have been disinterred scores of times or, quite possibly, has been invented by those who have heralded it as a new device. Its latest appearance as something original is in a recent issue of a New York photographic paper. None the less, it is a plan which may often be employed with advantage in the case of negatives of interior subjects in which most probably windows or other brightly lighted parts have become too dense in the developer. In place of risking the negative by reducing or rubbing down the more opaque parts, an ordinary reading-glass of about three inches diameter may be held in front of the negative during printing and, while kept gently in motion, caused to concentrate its light upon the part which needs help. The American writer prefers to fit a disc of black card with a hole in it in the rim of the glass and so to obtain the utmost concentration of light.

THE LONGEVITY OF PHOTOGRAPHIC PRINTS IN RELATION TO RECORD AND SURVEY WORK.

A RECENT dictum of the Camera Club indirectly revives the question of the permanence of different printing processes to be used as records by photographic survey and record societies. Perhaps the most widely understood meaning of the word "permanent," applied to everyday things, appertains to unalterability, but in photographic circles when questions arise as to the relative permanence of different printing processes their respective "durability" is generally meant and is so understood. Degrees of unalterability is rather a contradiction in terms, whilst durability may widely vary. To put the matter bluntly, if any printing process will afford lasting results for, say, a dozen or so years and upwards, it is generally considered to be permanent in the restricted sense alluded to. But the matter is on another footing when photographs are to serve as records for posterity, for here it is not enough that they should last for fifty or even a hundred years, but a life is reasonably demanded limited only by the holding together of the picture supports. By general consensus of opinion two commercial printing processes only, or variants of them, fulfil this condition. The life of silver prints at the best is one of conjecture, which the lapse of time only can settle, and many are known to be more or less evanescent. In the case of photographs utilised purely as records their useful existence is longer than for most other purposes: if discoloured or partially faded, so long as all details are preserved, they serve their purpose. On the other hand, when once deterioration has begun it often proceeds apace.

Though all are agreed that complete fixation and thorough washing are essential elements in the stability of silver prints, yet it cannot be said that deterioration can only be ascribed to these operations being scamped,

and there may be operative causes which are quite unsuspected. Printers of the old albumenised paper have narrated how prints known to be hurriedly fixed and washed have sometimes long outlasted those which had received orthodox treatment. In past days albumenised prints appear to have been overwashed, as in addition to prolonged changes by hand they were frequently left to soak all night. Impure air, damp, impurities in the mount or mountant, or a mountant tending to turn acid or mouldy, are all known factors tending to alteration and fading. Even with one brand of paper puzzling differences in the durability of prints arise, one worker recording rapid fading, or other troubles, whilst another experiences just the opposite. Inquiries often fail to reveal any variation in procedure to account for such difference, which in some irrational way seems to be connected with the "personal equation" which looms largely in other directions.

In daylight silver-printing processes the image may be said to consist of something in the nature of a stain, whilst with bromide prints we have reduced silver in a fine state of division in gelatine, and the general opinion is that these are the most stable of all silver prints. The life of a dry-plate bears on the permanency of bromide prints, though we should expect the former to outlast the latter owing to the silver and gelatine being present in greater degree, and also to the fact that there is no paper to retain residual traces of hypo. Comparatively few old dry-plate negatives show unimpaired condition, but at Greenwich Royal Observatory there is no indication of fading in any dry-plate negatives of stars, although many date back more than twenty years. Doubtless scrupulous care was exercised in fixing and washing, and none have been intensified or even reduced.

Whilst nobody can place a limit on the life of a carefully made bromide print, which may last many a long year, yet the official pronouncement of the Camera Club that "a well-made, thoroughly fixed and washed bromide print is probably as permanent as a print in any other process" cannot be justified. The probabilities are against this conclusion, and at variance with the opinion of recognised authorities, and with the views of the great majority of photographers. In essence, the assertion is equivalent to saying that finely divided silver, vulnerable to many adverse influences, is as stable a substance as, say, lamp-black, or platinum black, both regarded as unalterable under every atmospheric condition, and respectively employed in the carbon and platinum processes. Having regard to the support and to the fact that the platinum image is in actual contact with the fibres of the paper, necessarily of the highest grade, a platinum print may present an advantage over a carbon when a long-distant future is concerned, but both can fairly be bracketed together as truly permanent photographic printing images. Neither, of course, exists commercially on the strength of this feature, but on the distinctive qualities associated with them. The extraordinary resisting properties of platinum prints were illustrated some years ago, when a number remained at the bottom of the sea for some months in a sunken warship and were eventually salvaged none the worse for the adventure. Subsequently shown at the Brussels Exhibition, they perished by fire. Although the image of a carbon print is not in contact with the fibres of the paper, the pigment is locked in insoluble gelatine, known to be most durable in its normal state, and presumably more so when tanned by the action of light. As to the danger of peeling, sometimes alleged to exist, all that can be said is that this is of the rarest occurrence, and when it does take place may usually be traced to the under-soaking of the transfer paper, or over-hardening of the prints by chrome alum or similar chemical, or to undue haste in drying. Preference, naturally, will be given to those

tissues which contain carbon pigment, however durable other pigments utilised may be.

If the opinion of those responsible for the recent utterance of the Camera Club is based on the undoubted fact that many bromide prints made years ago show not the slightest signs of alteration, this proves that the prints are long-lived, but affords no information as to their ultimate life. We have in our possession a framed silver print (apparently albumen) of French origin purchased over sixty years ago, made long prior to the introduction of bromide papers, and only during the last few years has it shown signs of deterioration, though continuously exposed to daylight, and occasionally hung on walls none too dry. Possibly in another twenty years or less the picture may have disappeared.

Granted that carbons and platinotypes are the processes for record work, which nearly all secretaries of photographic record societies fully recognise, yet the unfortunate fact remains that if these were insisted upon few prints would be received, as the majority of amateurs print in neither process. So such societies are practically forced to accept silver prints, and with no guarantee even that they have been thoroughly fixed and washed. Possibly a dry silver print hermetically sealed and kept in the dark might last almost indefinitely, but this is outside the region of practicability. However stored for access, it is impossible to prevent a limited circulation of air and of any impurities in it over the prints owing to barometrical changes. Dry-mounting on pure paper, and a coat of good varnish applied to the surface, should materially help towards longevity. In the case of subjects obviously valuable as records, the loan of the negatives might be sought to enable permanent prints to be obtained, but unfortunately funds are often not available for the purpose. We feel sure carbon or platinum printing concerns would charge on the lowest possible basis, and on inquiry have received from two well-known firms an unofficial intimation to this effect.

There appears to be no specific authority conferred on any local authority to enable a small grant to be made for such a worthy object. But when the record society becomes part of the public free libraries (as in most cases should be the case for convenient reference) the general powers of expenditure are available. These are by no means great under the existing 1d. rate, which leaves but little margin for the purchase of necessary books, to say nothing of other desirable acquisitions. Many towns, however, have proposed an advance in the rate to 3d., and if this materialises prospects will be brighter for the societies associated with the libraries, if not for the ratepayer.

We wish all good-luck to the scheme of the Camera Club, and commend our observations to its attention, and in doing so a gentle reminder may be given to readers everywhere not to forget their local survey and record in the approaching season. Upon the executive, as a rule, falls the major part of the work, cheerfully undertaken and with no hope of being personally thanked by posterity, but we would urge a large measure of contribution by the general body of photographers.

RECORD PHOTOGRAPHS OF LONDON.—The writer of "Under the Clock" in the *Daily News* hopes that photographers taking part in the Camera Club scheme "will refuse to confine their energies merely to recording street scenes. A flashlight snapshot of an elderly gentleman making his sixth attempt to board the Tube at Piccadilly Circus, or a sympathetic study in carbon of a newly married couple recuperating at the seaside after a week of house-hunting, would be no less appreciated by the historian. The nervous tension of the City could perhaps be broadly suggested by an artistic rendering in gum-bichromate of Mr. J. H. Thomas's smile on being told by his aerial chauffeur, at 10,000 ft. over the North Sea, that he had decided to strike."

A BICHROMATE-MERCURY INTENSIFIER.

It was while working under active service conditions that the experiments leading to the discovery of a new method of intensifying negatives was made. Some very brilliant results were required in the way of transparencies, and the only plates in stock of the size wanted were very stale, and though labelled "Process," would not give even ordinary printing density. So the only thing to do was to make the best possible, and then clear and intensify as much as possible. Lead was tried, but owing to the lack of proper washing accommodation, bad water, and also to the strong colour it gives to the very slightest trace of veil in the whites, it did not answer in this case. After trying every method that I could to persuade the "quarter-bloke" in charge of the stores to let me have the material without the usual circumlocution, and still not getting enough density, I began to experiment, and eventually found a method of greatly increasing the density without risk of stain provided that the negative was thoroughly fixed.

The procedure finally adopted was to bleach the negative in an acidified solution of potass bichromate (as for chromium intensification), and then, after washing for a short while, immersing in a mercury-iodide solution, and after a further wash to darken the bleached image in a sulphide bath; or else in a hydroquinone developer if there were any likelihood of subsequent reducing being called for.

I found that a lot of washing, after fixing the plate, between the various baths, was not essential to clean working, and the increase in density was far greater than I have been able to get with any other intensifier except lead. If the bichromate is not all out before the negative goes into the mercury bath, it comes out into that solution, but does not seem to affect its working.

Like the mercury-ammonia intensifier (which it easily beats for density-giving power) this new method can be worked without accurately weighed and measured solutions, but in that case it requires rather a lot of bottles. Being minus reference books or any accurate measures at the time referred to, I got

on quite well without, and did not find any appreciable difference resulting from varying strengths and proportions of ingredients of solutions. The way I arranged matters was, first of all, to keep a saturated solution of potass bichromate, of which a little was diluted for use as required, and a few drops of hydrochloric acid added. If this did not bleach it was poured into a jar, and a few more drops of acid poured in. This bleaching bath does not keep, so it was thrown away after use. The mercury-iodide bath, on the other hand, keeps well in the dark-room, and can be used over and over again. As I had no formula by me, I made a fairly strong solution of each of mercury bichloride and potass iodide. Then a little of the latter was put aside, and into the remainder I poured the mercury solution a little at a time, well stirring and shaking to dissolve the red precipitate that forms when these two chemicals are mixed. A point is reached when a little of the red powder fails to re-dissolve, and it was to get this into solution that the small quantity of the potass iodide liquor was kept aside. On adding this to the bulk the precipitate disappeared. This strong solution was kept for stock, and was used diluted, but both the stock and working solutions appeared to keep well.

The sulphide solution was made as required from the crystal, but there is no reason why a stock solution should not also be employed for this. The used liquor should not be kept after the same day, as in the case of bromide toning. It seemed difficult to get the image thoroughly sulphided right through, so that if the density was too great some reduction was obtained by simply immersing the negative in a hypo bath. Another useful point with this intensifier, as in some others, is that if the plate before sulphiding is seen to be too dense or the lines are veiled, a dip in hypo solution will clear it. Of course, this means another good wash before sulphiding, and it should be pointed out that these extreme methods of working are seldom suitable for anything but line work, as the unevennesses of the emulsion are usually very much accentuated by employing strong measures.

D. CHARLES.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
The Camera and the Lens (Jan. 10).
Managing the Sitter (Jan. 17).
Backgrounds (Jan. 24).
Studio Exposure (Jan. 31).
Artificial Lighting (Feb. 7).
Printing Processes for Portraiture (Feb. 14).

Studio Accessories and Furniture (Feb. 21).
The Surroundings of the Studio (Feb. 28).
Studio Heating and Ventilation (March 7).
The Postcard Studio (March 14).
The Printing-Room (March 21).
About the Reception Room (March 28).

HOME PORTRAITURE.

Work which comes frequently to some photographers and only at long intervals to others is that of taking portraits at the sitter's own home. Some firms specialise in it to the extent of sending operators long distances, poaching upon the territory of the local man. There is no more remunerative class of work than this if properly managed, and if the prints are of good quality, yet many photographers fight shy of it, and these, it is to be feared, are generally those who bungle the job. With regard to terms, these are largely governed by local conditions and the prices obtained at any particular studio, so that I will do no more than suggest that no additional fee be

charged for "going out." One does not make a charge for going out to take a house, a horse, or a dog, and there is therefore no justification for making a charge if the model happens to be a human being. I recommend, however, that an order for a decent amount be secured, say, at least for a dozen of the highest class of cabinets, as a condition of the special visit. The fact that no additional charge is made will often induce a delicate or infirm person to be taken at once, instead of postponing the matter on account of the weather or other cause, with the possible result of the order being lost through death or the action

of a more enterprising artist. It is an excellent thing, from a business point of view, to secure the *entrée* to as many good houses as possible, for, with a little tact, it is easy to obtain orders for views of the home interior and exterior, and often of horses, dogs, and other domestic pets.

To make home portraiture easy and successful the outfit should be carefully chosen. The old way was to put the studio camera and stand in a cab and to trust to finding a dark-room in which to fill in the plates. This is not a fancy picture. Years ago I did it many times for a first-class firm, and I believe many do it still. The latest idea is to use a reflex camera—which has its advantages—but, on the whole, I prefer a stand camera, which is not only more adaptable as regards rise, swings, and the use of different lenses, but impresses the sitters with the idea that the work is being done properly, and that they are not being "snapped" with a portable camera, like Cousin Jim uses. Personally, I prefer a light parallel-bellows camera for whole-plates, fitted with a 12-inch $f/5.6$ lens. I also carry a Dallmeyer 2B portrait lens, which is useful for children or in very badly lighted rooms. The shutter—a Packard Ideal or a Guerry double flap—is fixed inside the camera. Usually six slides are carried, filled with such sized plates as the order calls for. It is, however, a good plan to have a couple of whole-plates in one of the slides, in case there is not sufficient room to get in the desired amount of the figure, although the order may be for cabinets only. The 2B, however, will give a three-quarter figure in quite a small room. The stand is an ordinary three-fold tripod, but rather heavy, and provided with the folding wooden base so often described. This latter is a very useful addition, as not only are the feelings of the housewife relieved when she sees that it is not proposed to stick spikes into her rugs and carpets, but it permits of the camera being moved by sliding, instead of lifting, thus saving much time and labour.

Sometimes it is desirable to carry a small background, best a double-sided one of light and very dark grey, about 5 ft. by 4 ft., upon two light rollers; it does not weigh much and is easily carried. A piece of calico to serve as a reflector is also useful, but if more impedimenta are not objected to, one of the Kodak portable reflectors may be substituted with advantage.

Now we come to the most important part of the business—the placing and lighting of the sitter. In rooms which are lighted by only one window the choice of position is limited, unless the window is unusually large and high. With small windows it is necessary to place the sitter close to the window to ensure the light falling at the proper angle, which should be as nearly as possible the orthodox forty-five degrees. It is surprising how nearly studio lighting may be approximated to if this be done. One important preliminary is to cover the lower part of the light with opaque material, and if the outside light is very strong, the upper part should be covered with a translucent fabric, nainsook for choice. Butter muslin is sometimes used, but it is too open in texture for direct sunlight. In practice I find it convenient to sew the two pieces of stuff together, the upper half being a piece of nainsook about 4 ft. wide and 5 ft. to 6 ft. long, and the lower black or dark green sateen, the same width, and about 4 ft long; this allows for windows which go down to the floor. This curtain is easily fixed in position with three or four push pins, any surplus length at the top being closely folded or rolled and pinned through. In a dull light the white half may be folded down behind the dark part and the clear glass used.

As the conditions do not vary greatly in this class of work, the inexperienced photographer will do well to make a few exposures in an ordinary room at home and note upon the prints the positions in which the camera and sitter were placed to get the different effects; some will probably be good and more probably some will be bad, and, by selecting the more successful ones, he will find out the best way of working. For ordinary three-quarter lighting the sitter must be placed about

2 ft. back from the edge of the window and about 3 ft. into the room. This distance will vary with the height of the window; if the room be very lofty, the sitter may come further in and still be well lighted. Only in very lofty rooms should full lengths be attempted, otherwise the angle at which the light strikes the head is too small and the shadows of the features are flattened and the eyes filled with light. In some large houses, where the windows are 12 to 14 ft. in height, studio effects are easily got. For plain lighting the camera should be kept as near to the window side of the room as possible, but for other effects it may be placed in many other positions. The so-called Rembrandt lighting is easily got in an ordinary room, more easily than in most studios. In this style the wall at one-side of the window carries the background. Here the dark grey ground will be very useful; the sitter looks straight across the light, which should give a broad line of light down the profile. By turning the head, a little light may be allowed to fall on the cheek-bone, but this is a matter of taste. The shadow side of the face which is turned to the lens should be lighted up by the reflector, which must be near the camera; in fact, it is sometimes an advantage to cut a hole in the reflector for the lens to look through.

There are great possibilities in the use of an ordinary looking-glass, especially in small rooms, and when photographing invalids in bed, as by its aid the sitter may turn his face towards the window and still present the lighted side of it to the camera. In the very difficult case of a sitter in bed in a small room, the mirror may be so placed as to enable the photographer to work through the doorway. It should be remembered, as far as the working distance is concerned, that this is made up of the distance from sitter to mirror, plus the distance from lens to mirror, so that in a room where it is only possible to get 3 ft. between lens and sitter by the use of the mirror, the working distance may be double or more. It must not be forgotten that negatives so taken are laterally inverted—that is to say, that if printed in the ordinary way the hair will be parted on the wrong side; in fact, the image will be as seen in the mirror. To overcome this the prints may be made in single transfer carbon in Kodak transferotype bromide paper, or they may be printed in the enlarger with the glass side to the lens, or if portrait films be used, simply by printing from the back. Some objections to the use of the mirror may be raised upon the ground that there is the possibility of getting a double outline of the image, and this, of course, would occur if the mirror and lens axis were at an angle of, say, 45 deg. with each other; but when the lens and mirror are at right angles to each other there is no danger of this defect appearing.

The scope of home portraiture may be greatly extended by the use of artificial light, and I look forward to the time when the nitrogen filled or half-watt lamps will have entirely displaced the ordinary vacuum (?) type. We shall then be able to work where we like in the room and get fireside and card-table groups as easily as in the studio. Meanwhile we must rely upon magnesium, either in the form of the flash, or, as I prefer to use it for this class of work, in ribbon. Two feet of ribbon cut into four lengths and twisted into a torch give a light equal to an arc-lamp, and, if burned behind a diffuser, leave nothing to be desired in the way of lighting. There is no explosion, as with the mixed powders; no snowstorm, as when the pure metal powder is used; the flame is small, and there is no risk to draperies, the only precaution necessary being the provision of an old tea tray or mat to catch any burning ash which may drop from the torch. I always carry a roll of magnesium ribbon in my camera case with a bit of sandpaper to brighten it with and a wooden clip to hold it while burning. Do not try to light oxidised ribbon; it is a slow job; brighten it with the sandpaper and then it lights quickly and burns evenly.

TRAINING THE RETOUCHER.

The incompetence of a large proportion of retouchers is a fact which many photographers know too well. This deplorable state of things is chiefly due, I consider, to the sloppy methods of instructing that are in vogue in the profession. Much valuable time is wasted in having to inspect the work of such assistants before it goes to the next department, whereas it ought to be expected of them to be competent enough to pass it along through all departments until final inspection. I advocate the giving of a short allotted time and direct personal attention for a few days as a huge time-saver in the long run, and as an aid to high quality.

The majority of assistants do not know what retouching exactly should be. Generally speaking their knowledge does not go beyond the idea that they must aim at a decent stipple. What should be done, or what to do for the greatest improved effect with the least possible amount of labour, and how it affects the next department (i.e., the enlarging and "finishing" artist) they lack knowledge of. In some cases masters lack knowledge of art principles and their application. Retouching taught without these, in my opinion, is absolutely valueless. Supposing the method usually adopted in training a pupil for retouching was applied in the darkroom or printing-room, disaster would sooner or later happen to a batch of work or soon tell its tale by the work not proving permanent. Naturally the first thing one does in these rooms is to explain the reasons for doing certain things.

Some sort of guidance in theory ought to be in vogue among all photographers—who have the profession at heart—beyond that of the mere making of money. The pupil wants a thorough knowledge of what is required in the branch he is being instructed in. One would not look at the end of a pencil to draw a straight line, otherwise there would be no means to the end in getting that line straight. The mind judges where that line should be to be straight and the brain directs the hand accordingly. It cannot be said that the hand directs the pencil to make the line straight; if the pencil is held correctly the mind draws the straight line. I take this principle as illustrative of my method of instruction for retouching. A negative cannot be retouched unless the whole effect required is in one's mind. How to hold the pencil is half the battle. I have noticed that retouchers who hold their pencils at right angles to the negatives and the forefinger tightly in the shape of a triangle are usually bad workers and their stipple is wormlike and has no symmetry. This is caused by their being unable in this manner to work the fingers freely, the guidance having to be done by the arm and wrist, making the arm an eccentric.

The correct style, and one which saves hours of labour for the finishing artist, is to hold the pencil very loosely between the thumb and first two fingers, and almost perpendicular, thus using the side of the pencil point and obtaining any desired angle of movement above the wrist by the fingers (the little finger resting on the negative). Never mind how you get a stipple so long as you work to follow the lines of the muscles of face and texture of the skin of the sitter, not to smother the negative. Many so-called expert retouchers (stiplers) place a beautiful sheen of lead all over the face, whether it be old man, lady, or child; in reality, a lead wash, such as a painter employs as a ground-tint. It is an absolute waste of time, and the effect mechanical, causing many a master to employ two retouchers where one would suffice, and giving an effect which is artistically and commercially valueless. Aim at altering defects only and improving the artistic value by the following course: Select your pupil and give half an hour's personal instruction each day for a week, first getting the pupil to master the taking away of complexion blotches and spots. Aim at nothing else until the pupil can do these to match the surrounding ground without overlapping.

The next step is to instruct where the muscles are exaggerated by the necessary side-lighting of the studio. With a satisfactory stroke there should be no so-called stipple. Then get your pupil to look at the whole of the face and imagine the negative as a line drawing in the positive sense, considering exactly what lines would be drawn to represent the character of the person (dismiss the half-tones for the moment). Get the pupil into the habit of bearing in mind the curve of the main lines that represent the character, such as the shape of the nose, main lines of lips and eyes. Any small complementary shadows there are to these do not need retouching. The next to consider is the relation of the strong highlights to the imaginary line drawing, and in doing this treat all the half-tone lights as that of a thin wash of paint an artist would put over his drawing. They need no altering, only blending into the main lines (i.e., massed shadows). The direct alteration of any half-tone or massed shadow representing the line of the facial muscle is fatal in retouching. These are the chief points to consider for artistic retouching. Any other work such as squaring noses and altering nose shadows are not necessary, if the face is properly lighted. All that is needed is the minimum work and the maximum result, which is only obtained by keeping the whole face in mind all the time. Try this method on your next pupil as against the old style of practice—practice without aim—and you will be surprised at the result and time saved. GEO. F. BURRELL.

THE POSTCARD LANTERN AS AN AID TO COPYING AND ENLARGING.

A POSTCARD lantern or its equivalent, for a simple substitute is quite easily devised, will often prove of use to the photographer for special work. It may be of great assistance, for example, when one desires to make a copy or an enlarged negative from a print, while at the same time introducing modifications, or blocking out unwanted portions.

Direct enlarging with a postcard lantern is not new, having in fact been suggested by A. E. Swoyer, in the "American Annual of Photography" for 1914. That writer, however, regarded the projected image as an end, whereas in the present article it is simply a means to an end or intermediate stage, while the method adopted is entirely distinct.

It will be seen, by reference to fig. 1, that the postcard lantern consists of a body, A, in the front of which is fitted the objective, B, while at the back is a hinged door, C, with grooves to hold the print, or sometimes a sliding carrier. A good source of illumination is two 30 c.p. or 50 c.p. metal filament bulbs, D and E. The inside of the body is whitened, and it will be noted that the sides nearest the lamps are at such an angle as to reflect the light

on the print. Two small interposed screens, or some similar arrangement, prevent direct rays reaching the lens. Cowled chimneys are usually fitted over the lamps, and due provision made for ventilation.

Fig. 1.

The most important item is the lens, which should be of fairly large aperture, owing to the loss of light by reflection, and should have a flat field. Cheap postcard lanterns often have objectives with so round a field that the holder has to be curved to get uniform definition. Such a lens is, of course, quite unsuitable for copying or enlarging. Many of these objectives are not even

achromatic, and, on the whole, a proper photographic lens is much to be preferred, even to the best of them. The lens must be capable of covering a plate at least as large as the print to be projected, and the lantern should have sufficient focal adjustment or extension to render a fairly small picture possible when required.

There will be needed, in addition to the lantern, an easel of the type shown in fig. 2. This consists of a frame, A, containing a

Fig. 2.

sheet of plain glass, B, and supported in a vertical position by a firm base and struts. To the frame, A, is hinged a smaller frame, C, which, when closed and secured by a turnbutton, presses on the glass.

The print to be copied is inserted at the back of the lantern, and focussed sharply to the desired size on a sheet of tracing paper stretched taut between the two frames on the easel; or, if preferred, a piece of finely-ground glass may be placed in the frame, A, instead of a plain piece, and the tracing paper dispensed with. If the second course is adopted, the ground side of the glass should be at the back of the easel.

The worker, standing or sitting behind the easel, now has it in his power to modify the projected image considerably, by means of pencil or stamp work on the ground glass or tracing paper, and even the brush may be employed advantageously in some cases. Since the image is a positive, there is no difficulty in seeing exactly how the final result will appear. Care, of course, has to be taken that the work matches the colour of the image.

The next step is to make a negative from the modified image, by setting up a camera, F (fig. 1), behind, and central to the easel, G, without moving or interfering with the lantern. Thus, the copy negative will contain all the introduced work as well as the essential characteristics of the original, and the result, if all is well done, will be a considerable improvement. The negative may obviously be any required size, though preferably it should be smaller than the projected image, as this reduces the likelihood of grain showing.

It will be seen that this method affords a handy way of inserting a black background, by painting round the projected image with any suitable opaque; or of introducing accessories on an originally plain light background; copying joined-up prints and combinations; adding skies to landscapes; and many other purposes.

One may also make enlarged modified negatives direct from prints, by working-up the projected image, as before described, and then, having first covered the objective, placing a large plate in the frame behind the ground glass or tracing paper, the exposure being then given by uncovering the objective for an estimated time. In this case, the postcard lantern must evidently be light-trapped properly, which is not so necessary for copying with a camera; while a little extra space must be left in the rebate of the easel frame to allow the insertion of the plate. Enlarging in this way softens the definition a little, and thus lends itself to artistic effects. There may also be a slight grain, but with proper care this should not be objectionable. Backed plates should invariably be used.

Since metal-filament lamps do not give out much heat, it is quite feasible, with an intelligent study of size and ventilation, to construct a simple wooden lantern of the kind under discussion; or, with but a little adaptation, one or other of the various contrivances for enlarging by reflected light without a condenser may be pressed into service.

To anticipate a difficulty which may, perhaps, perplex some

who are unfamiliar with postcard lanterns, it should be stated that the projected image is always laterally reversed. Viewed from the rear of the easel, however, there is no inversion, which explains why copying is done from the back, that also being fortunately the most convenient position.

A. LOCKEIT.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

THE NEW PRESIDENT.

At the annual general meeting of the Professional Photographers' Association, held on March 14 last, Mr. H. A. St. George was elected president for the ensuing year. Mr. St. George is a partner in the firm of Henry Dixon and Sons, of Albany Street, London, N.W., photographic copyists of paintings and other works of art. He has been a member of the council of the Association since 1912, and

H. A. St. George, Elected President Professional Photographers' Association March 14.

as one of the younger members of that body, and, moreover, as one whose business enables him to take a somewhat more detached view of conditions in portrait photography, it may be expected that the Association will benefit by his presence at its head in the discussion of problems which are likely to arise during the next few years. It may be hoped, too, that under his leadership some beneficial result may be reached in the way of forming a stable and influential group of commercial photographers within the P.P.A. as a means of protecting the interests of the increasing number of photographers in this branch.

ANNUAL GENERAL MEETING.

The annual general meeting was held at the rooms of the Royal Photographic Society, 35, Russell Square, London, W.C., on Friday, March 14, 1919, the president, Mr. H. A. Llewellyn Chapman, (Swansea) in the chair.

The minutes of the last general meeting having been read and confirmed, the president asked for nominations of scrutineers of the ballot papers. Messrs. Wedlake and Skillman were appointed. The ballot papers were thereupon handed to these gentlemen, who withdrew to carry out their work.

The hon. secretary read the annual report of the council (already published in the "B.J.," February 28 last).

The adoption of the report was moved and seconded by Messrs. Illingworth (Northampton) and Ellis (London). In a general discussion of the report which followed, Mr. Chapman (Swansea) congratulated the Association upon the accession of 151 new members during the year, and urged the claims of the Association upon the profession generally. He said that he would not be satisfied until every professional photographer worthy of the name had joined their body. He was only reiterating the advice of the "British Journal of Photography." A congress during his year of office had been impossible, but there were good grounds for anticipating one in 1920, and he hoped it would be well supported. A congress was essential to the professional. It helped everyone. It helped photographers who were able to attend, it encouraged those who could not attend, and made them wish to do so another year. It helped the trade. It made business. It broadened everyone's ideas and sympathies, and by bringing men together it helped to create that brotherly feeling which was advantageous to all, but especially to those who followed the art and craft of professional photography. He looked forward with great expectation to the time when he would be able to greet his brother artists at the next congress.

Mr. Hands (Wanstead) said that commercial photographers required the assistance of the Association principally in the direction of determining prices. He meant that advice was required in this class of business as to the proper charges which a photographer ought to make.

Mr. St. George (London) related the efforts which had been made to form a branch to deal more particularly with the business of commercial and technical photography. Their success had not been commensurate with their efforts, but he would endeavour during his year of office to encourage the members interested in that particular branch of the trade to come together to protect their own interests. The P.P.A. would help them to the utmost of its power.

Mr. R. N. Speaight (London) hoped that the matter could be dealt with in the Circular. It would be useful to many.

At this stage of the proceedings the President stated that, owing to the exigencies of the train service—he having to return to Swansea that evening—he would ask the indulgence of the members to alter the order of the business. He proposed at once to induct the president-elect into the chair. This would enable him to catch his last train. His year of office had been a very pleasant one; he had been shown the greatest courtesy, and he thanked the members very sincerely for the honour they had done him by electing him president.

With customary ceremonial the retiring president then inducted the newly-elected president into the chair, and placed the badge of office around his neck.

Mr. H. A. St. George then said that his predecessor, although living so far from London, has attended many meetings of the council, and has taken a keen interest in the proceedings and welfare of the Association. He himself would endeavour not to fall behind him in either sense. The war had come to an end, and they all hoped to have a new England, and incidentally an invigorated P.P.A. When his term of office expired, he hoped to leave the Association better and more prosperous than he had found it. There was plenty of work in sight. The increased prices of photographic materials had placed the conduct of photographic business upon a new footing. The status of photography must be maintained and improved. No one had foreseen the important part which photography would play in the war, the material help which it would give to the successful prosecution of the war. Great alterations were possible in photography, and the members of the Association could help these things to materialise. As president he would help with all his power; but he, or others in his place, could only do a small part—the bulk of the motive power must come from the members themselves. Members, more members, and still more members must be the motto. He hoped a congress would be held in 1920; let every member advertise it as widely as possible, and work for it to ensure success. He thanked the members for the confidence they had placed in him by electing him, and promised that what he could do he would do.

Mr. Ellis then moved, and Mr. Speaight seconded, and it was unanimously agreed, to accord a hearty vote of thanks to Mr. Chapman, the retiring president, for his services to the Association during his year of office.

Mr. Read (Southport) asked to be informed as to the number of members who were not master photographers; how many members were managers. There were great controversies now in progress about assistants. He thought it necessary to ask how many assistants were members (as managers) of the Association.

The Hon. Sec. thought that 95 per cent. of the members were master photographers.

The Hon. Treasurer then dealt with the statements of accounts. He hoped that members would think the figures satisfactory, and the arrangement of the figures clear. He had few comments to make. The number of subscriptions was the largest recorded. The expenditure had been carefully watched and no extravagances indulged in.

Mr. Rigden (London), the hon. auditor, discussed the form of the accounts, his principal criticism being directed to the manner of dealing with subscriptions paid in advance; and he made suggestions as to a better method. The Hon. Treasurer said that he had carried out the traditions as he had received them from his predecessors in office, and added that the Council would consider Mr. Rigden's suggestions, and decide how the accounts should be presented another year.

Mr. Ellis (London) then moved, and Mr. Illingworth (Northampton) seconded, and it was resolved unanimously that the statement of accounts, as printed, be adopted.

Messrs. Rigden (London) and G. W. Cooper (London) were appointed as honorary auditors for the ensuing year.

An alteration of Rule 5 was proposed by Mr. Read (Southport), and seconded by Mr. Cooper (London), to read as follows:—

That the annual subscription be raised from 5s. to 10s., payable in advance.

Mr. Rigden moved as an amendment, which was seconded by Mr. Hana:—

That in the case of members whose rateable value does not exceed £50, five shillings may be accepted.

The original motion was carried by a large majority.

Votes of thanks were accorded to Mr. Rigden for his services as hon. auditor, to Mr. Mackie for his work as hon. secretary, to Mr. Fry for his work as hon. treasurer, to the Council for their work for the Association.

The Scrutineers (Messrs. Wedlake and Skillman) reported the result of the ballot as follows:—

PRESIDENT.

H. A. St. George (London).

PAST PRESIDENT.

H. A. Llewellyn Chapman

MEMBERS OF COUNCIL.

London.

Basil, A.
Chase, Gordon
Corbett, Alexander
Dickinson, C. F.
Ellis, Alfred
Fry, S. H.
Gray, W. E.
Haines, Reginald
Hana, George
Sims, Lang
Speaight, R. N.
Wakefield, F. W.

Country.

Adams, Marcus (Reading)
Beaufort, J. W. (Birmingham)
Brown, F. (Leicester)
Chaplin, W. B. (Windsor)
Chidley, Thos. (Chester)
Cooper, Montague (Taunton)
Illingworth, W. (Northampton)
Lanckester, P. (Tunbridge Wells)
Read, F. (Southport)
Spink, H. C. (Brighton)
Turner, T. C. (Hull)
Watson, A. Swan (Edinburgh)

The work of the scrutineers having occupied the whole of the evening, a very hearty and exceedingly well-deserved vote of thanks was accorded them unanimously.

THE POPULAR ENLARGING COMPANY, of 41, High Street, Islington, London, N., in entering the ranks of firms making enlargements for photographers, recently asked us to inspect their premises and judge for ourselves the facilities of the firm for turning out their work with reasonable promptness. We found that the firm has put down a good and well arranged little plant, and judging from the specimens employed in its own portrait business, can offer very satisfactory service to photographers requiring the enlargements in general demand among middle-class studios.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, March 17 to 22:—

- ROTARY PHOTOGRAVURE.—No. 6,602. Means for mounting photo-gravure cylinders. J. P. Bland.
 DEVELOPING TANKS.—No. 6,971. Developing tank. F. Brodrick.
 PHOTO-MICROGRAPHY.—No. 7,047. Photo-micrographic apparatus. S. W. Ross.
 PROJECTION SCREENS.—No. 7,204. Cinematograph, etc., screens. M. Hurd.
 CINEMATOGRAPHY.—No. 6,571. Rotating shutters of cinematograph projectors. A. Kur.
 CINEMATOGRAPHY.—No. 7,026. Cinematography projectors. T. E. C. Wheeler.
 LIGHT TRANSMISSION.—No. 7,041. Process for creating variations in relative, normal, refrangibility, or velocity ratio of light-transmission through or from differing refracting media. H. Soar.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

- LANTERN SCREENS.—No. 121,409. (April 26, 1918.) A surface covering of finely divided particles of mica or quartz is given to the screen by employing a suitable size or medium, so that it may be applied by means of a brush; this greatly increases the quantity of light reflected from the portions illuminated without detracting from the effect of the shadows; it also reduces the amount of light required to illuminate the screen, adds depth and distance effect to the picture, and makes it possible to reproduce on the screen the brilliancy of natural sunshine and other lighting effects. Charles Frederick Kirby, Oakhurst, 57, Ashbourne Road, Derby.
- LANTERN SCREENS.—No. 117,053. (March 14, 1918.) A silvered screen is veiled by two separate screens, with spaces between, these veiling screens being composed of netting silvered on the front. The construction of the screen is as follows: The back screen is composed of plaster or fabric or the like, silvered over on the front. Over this back screen is placed a veiling screen with a space between them; this veiling screen is composed of a fine mesh netting or the like, silvered over on the front side and black on the rear side. In front of this veiling screen is placed a second veiling screen with a space between them; this second veiling screen is composed of a fine mesh netting or the like, silvered over on the front side and black on the rear side. Frank Heale, Kingswood, Gipsy Lane, Putney, S.W.15, and George Wallace Bryant, 183, Victoria Road North, Southsea.
- DYED CHEMICALS.—No. 105,920 (April 25, 1916). All photographers know the difficulty which exists in knowing when the elimination of chemical substance such as sodium hyposulphite has been reached. According to the present invention this difficulty is met in a very simple manner. For this purpose during preparation there is added to the reagent, which is afterwards to be eliminated by washing, a suitable colouring material, such, for example, as an aniline dye, chosen and carefully proportioned in such a manner that the colouration which it imparts to the emulsion disappears by washing at the same time as the last traces of the deleterious substances are eliminated. It will be understood that different colours are preferably chosen for different reagents which helps in the avoidance of any errors in the use of these reagents.
- The method of preparing the chemical substance employed consists in incorporating the various photographic reagents and the colouring material in a finely divided condition in a syrupy or viscous liquid, soluble in water, such as syrup of sugar, glucose, glycerine, alkali silicates either alone or mixed together, and in

general in all other suitable substances whether neutral acid or alkaline, according to requirements, in so far as they possess the property of preserving indefinitely a pasty form. Pastes thus formed are preferably enclosed, in known manner, in collapsible tubes of tin, or any other analogous or suitable material, these tubes if required being coated internally with an insulating or protecting varnish whenever the substances used are liable to attack the metal. The preservation of the reagents and colouring matter is thus doubly assured, as in a tin tube they are always protected from the atmosphere.—Alfred de Brayer, 38, Rue Etienne Marcel, Paris, France.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

- VOLETTE.—No. 387,774. Photographs and photographic papers. Albert Drummond Shiels, Thornhill House, Wishaw, Scotland, photographic artist. January 22, 1919.

New Books.

The Theory of Modern Optical Instruments. By Dr. Alexander Gleichen. Translated from the German by H. H. Emsley, B.Sc., and W. Swaine, B.Sc. (London: His Majesty's Stationery Office; for the Department of Scientific and Industrial Research. 12s. 6d. net.)

WHILE the achievements of British makers of optical instruments during the past fifty years have been by no means inconsiderable, the British literature of the subject has been scanty in the extreme. Whether that has been due to a large measure of resort here to rule of thumb and trial-and-error methods, or to our opticians taking their theory directly from the works of Continental writers, we will leave others to decide. In either case, the Department of Scientific and Industrial Research has done very rightly in seeking to endow optical technicians and students in this country with theoretical treatises in their own languages, and in default of corresponding works by English writers has selected several German text-books for translation. Dr. Gleichen's is the first of these to be issued; that by Dr. von Rohr on "The Theory of Optical Instruments" is to follow shortly.

It should be made clear that Dr. Gleichen's work is one on concepts—that is to say, on the expression in a form for practical use of the known facts of optics. It is a work of a kind which seeks to convert the wealth of optical knowledge into current coin which can be conveniently handled and render useful service. Therefore, the student who is interested simply in the physical facts of light will find little to attract him, just as a student of economics is not interested in accountancy or the technics of banking. The first part of the volume is devoted to a general consideration of the optical principles of image formation from the standpoint of providing formulae for optical conditions of tracing the action of optical systems and of finding means for specifying them quantitatively. The properties and construction of photographic lenses form only a small part of the field which is covered, and in some respects appears to be the least satisfactory part. More than half of it is taken up by a very partial review of the types of anastigmatic objective, every one of which is of German origin. The book was written in 1910, so that one can hardly assume a want of opportunity for the author to have heard of British anastigmata. The only indirect reference (on p. 74), by omitting the name of the "Cooke" lens, makes it appear as though Mr. Dennis Taylor designed this objective for the firm of Voigtlaender. The passages dealing with the telephoto lens are equally—shall we say?—inadequate, historically. The translators, who in many footnotes greatly add to the value of the book, might very well have had a correcting word to say here, but it would seem that photographic lenses and photography are not their familiar ground. Their sentence that a certain lens is intended for "autochromatic work" may be a slip of the pen, or the phrase of one rather strange to photography. Nevertheless, for its treatment of the theory of the properties of a photographic lens, the book well deserves a place in the photographer's optical library.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, APRIL 5.

Hackney Photographic Society. "The Importance of Photography in the War." A. Dardon-Pyke.
Rodley and District Photographic Society. Social Evening.

SUNDAY, APRIL 6.

United Stereoscopic Society. Social and Musical Evening.

MONDAY, APRIL 7.

City of London and Cripplegate Photographic Society. Members' Print Competition.
South London Photographic Society. Annual General Meeting.

TUESDAY, APRIL 8.

Royal Photographic Society. Special Meeting for Members only.
Chelsea Photographic Society. "A Journey to Rome." C. Pretty.
Hackney Photographic Society. "Some Things Seen in Holland." W. Rawlings.
Manchester Amateur Photographic Society. Monthly Meeting. "Bird Nest Photography." R. H. Blair.

WEDNESDAY, APRIL 9.

Croydon Camera Club. A Display of Novelties and Home-made Apparatus.
Hford Photographic Society. Demonstration: "Compensators." R. H. Lawton, F.R.P.S.
Dunston Amateur Photographic Association.—Composition. J. Huck.
Photomicrographic Society.—Members' Evening.

THURSDAY, APRIL 10.

Hammersmith (Hamphshire House) Photographic Society.—"Carbon Printing." A. C. Ibrahim.
Hull Photographic Society.—Annual General Meeting.
Chelsea Photographic Society.—"A Journey to Rome." C. Pretty.
Richmond Camera Club. "Some Experiments with Polarised Light." F. C. Reynolds.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, April 1, Mr. E. W. Mellor in the chair.

Mr. S. Bakerseff read a paper on "Commercial photo-copying processes" in which he dealt first with the various iron-printing papers employed in the making of contact copies of engineers' tracings and drawings. He gave brief working details of the ferro-prussiate or white-line paper, the ferro-gallic or black-line paper, and the cyanifer or Pellet process producing copies in blue line on a white ground from a tracing. The sepia process, as he pointed out, was one which is useful in making a negative copy from a tracing and thus allowing of a number of blue-line prints being made on the ordinary ferro-prussiate paper. For making inscriptions, etc., in white on the blue ground of a ferro-prussiate print he recommended a saturated solution of sodium carbonate, preferably the concentrated form of the carbonate sold as soda ash. The solution should be thickened with a little gum in order to prevent it from spreading. Arising out of a question in the subsequent discussion, Mr. Bakerseff said that the sodium carbonate solution did not give a perfectly white lettering, but the faint buff colour was sufficiently white for the purposes of architects and engineers. Comparing the two varieties of ferro-gallic paper, water-developing and that which is developed in a gallic acid bath, he pointed out that the latter was the variety to be chosen for use in tropical countries on account of the better keeping qualities of the sensitive paper.

The lecturer proceeded to show photographs and diagrams of the various types of machine introduced of late for the printing of these papers from tracings, etc. He said that the most technically perfect machines, in his opinion, were those designed by the Westinghouse Cooper Hewitt Company and employing mercury-vapour tubes as the illuminant. He described the working of stationary and rotating machines of this company, referring to the electrical devices by which the mercury light could be started without tilting the tubes.

In the later portion of his paper he dealt at very great length with the details of construction and manipulation of the Photostat copying installation.

Following a brief discussion the hearty thanks of the meeting were accorded to the lecturer.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the Council was held on Friday, March 14, 1919. Present: Messrs. Adams, Basil, Chapman, Chaplin, Chidly, Corbett, Dickinson, Ellis, Fry, Gray, Haines, Hana, Illingworth, Lang Sims, Speaight, Spink, and Mackie.

The minutes of the last meeting were read and confirmed.

Accounts amounting to £44 were passed for payment.

A letter from Mr. T. C. Turner (Hull) was read regretting his inability to attend.

A letter from Mr. Montague Cooper (Taunton) was read, pointing out that the list of attendances of members of Council was not correct, and making other suggestions and criticisms. The hon. secretary informed the Council that he had checked all the attendances and had found them correct, and that he had written to Mr. Cooper to that effect.

The hon. secretary read a letter from Mr. James Webster, hon. secretary of the Otago Professional Photographers' Association, with reference to the formation of that association, and enclosing a photograph of some of the members.

A letter was read from Mr. Rigden (London), the hon. auditor, relative to the accounts, and it was resolved that Mr. Rigden be asked to make his suggestions to the annual general meeting.

A letter was read from Mr. Owers (Southsea) endorsing the action of the Council in proposing to raise the subscription.

A letter was read from Mr. Heineman, of Plate, Ltd., Columbia, stating that he had advertised in the "British Journal of Photography" for assistants, and desired the assistance of the P.P.A. in the matter of interviewing the applicants. Mr. Hana (London), and Mr. Illingworth (Northampton) undertook to see the applicants on the correspondent's behalf, the hon. secretary to inform the applicants when he received a communication from them.

CROYDON CAMERA CLUB.

MR. W. F. SLATER, F.R.P.S., arrived last week with "Useful Odds and Ends," including a finely developed cold, doubtless due to a tonic spring. He dealt interestingly and instructively with many things, fully described some short time back by the conscientious reporter of the South London Society.

However, one neat idea shown by him at Croydon was only hit upon the day previous to his auspicious visit. It consisted of an enamelled metal dish and container, by which hypo is compelled to abandon its tendency to skulk at the bottom. The dish proper has a series of V notches cut out of the top of two opposite sides. Inside the dish is placed a rectangular framework or container (practically a second "dish" without a bottom) of the same height, but of appreciably smaller area. This has inverted V notches, cut out of the bottom of two walls opposite each other. The prints are washed in the container, and the hypo is discharged through these notches and out of those in the outer vessel. The idea was considered very good, and a suggestion was made that an ordinary granitine dish might be used for the outer vessel if the walls of the container were higher than the dish.

To imagine Mr. Slater giving a demonstration on any subject without a passing reference to his beloved "time developments" would be an unworthy thought. He showed a most convincing set of prints from negatives of the same subject, which had received exposures in ratio 1 to 32. The negatives were all developed in a standard developer for a standard time at a standard temperature. If any other standards have been inadvertently overlooked, standard apologies are tendered. The topic, of course, drew criticism from those who believe standardisation is not invariably the best procedure for unstandardised subjects. On the other hand, Mr. Jobling who went off like an automatic, merry and bright, supported Mr. Slater strongly, but, mistaking his precise views, expressed a confident opinion that a varying period of development was necessary for subjects of varying contrast. Any who maintained the contrary were indisputably balmy. "Save us from our friends!"

But what led up to the most festive time was a statement made by Mr. Slater that if a passing cloud obscured the sun exposures for shadows would be less than when they were cast by direct sunlight. The point is not new, and it has been suggested that the untimely demise of Abel arose out of a discussion on the subject. If he originated and formulated it on Mr. Slater's lines the sequel is hardly to be wondered at.

Mr. Salt said, assuming the cloud to be only sufficiently large to cover the sun, he failed to see how the shadows were lightened. Retiring on various appeals that he should consult a mental specialist, others took his place. A terrible conflict of views followed, not due to any real difference of opinion, but merely owing to the mental muddle established, in which three distinct aspects lost independent existence, for clouds can obstruct, diffuse, or

fect the sun's rays. The Chairman, Mr. Harpur, said he agreed with Mr. Slater. A simple experiment would prove the case. Let a piece of white and a piece of black paper be regarded in direct sunlight. The white will appear an intense white and the black "black." (Hear, hear.) Now let the light be diffused, and it will be found that the contrast between the two will also be reduced. "My hat!" exclaimed a member in despairing accents, in ignorance, no doubt, that Mr. Harpur was probably basing his contention on the old proverb: "All cats agree in the dark."

A most hearty vote of thanks was accorded Mr. Slater for a capital evening. For three weeks now the club has compulsorily run on the noble "dry" ticket. No noticeable improvement has been observed in any direction, and in English as she is spoke a marked deterioration has occurred. If only the party nominally responsible, Mr. Inskeep, would take a tip from the "movies," and with a six-shooter tickle the lower waistcoat of the club's wine merchant, things might revert to the normal.

Commercial & Legal Intelligence.

LIMITED PARTNERSHIP.—Registered March 22. E. Fresco, photographers, 181, Oxford Street, W. Partnership for one year from January 1, 1919, and thereafter for so long as partners agree, provided lease of above premises is extended. General partner: E. Fresco, 230, Shaftesbury Avenue, W.C. Limited partner: Louis N. Viola, 6, Great Russell Street, W.C., contributing £150 in cash.

BALHAM PHOTOGRAPHER'S AFFAIRS.—At the offices of the Official Receiver for the Wandsworth District, York Road, Lambeth, last week, the first meeting of creditors was held under the failure re Charles Frederick Michell, 121, High Road, Balham, S.W., photographer, against whom a receiving order was made on March 18, 1919.

The statement of affairs filed by the debtor showed gross liabilities amounting to £256 8s. 6d. of which £232 18s. 6d. was expected to rank against the estate for dividend. The net assets were returned at £13 5s. 8d., thus leaving a deficiency of £219 12s. 0d.

The debtor alleged his failure to have been caused through keen local competition, onerous terms of agreement relating to the business taken over by him at 8, High Street, Tooting, want of capital and heavy expense incurred in attempting to work two businesses at the same time.

The Official Receiver's report on the case was to the following effect, that the debtor, aged 49, who was adjudged bankrupt on March 18, states that after serving an apprenticeship with a photographer at Swansea and subsequently working with him and other firms at Swansea and in London, he, in November 1917, started business for himself as a photographer at 8, High Street, Tooting, under the terms of an agreement entered into with the Art Studios, Ltd., whereby he took over the lease of the premises and agreed to pay an average rental of about £223 a year, payable weekly; to include rates and taxes and the use of the photographic appliances, shop fittings, fixtures, and electric light. He had an option to purchase the lease and the appliances for £200, and paid (out of borrowed moneys still owing) a forfeitable deposit of £20, in respect thereof. He found three months after starting the business that it was not paying and took a vacant shop and house at 121, High Road, Balham, at a rental of £120 a year, in the hope that by working the two businesses together he might render them profitable.

On February 20, 1919, he informed the Art Studios, Ltd., he proposed to vacate the Tooting premises, but at their request, made for the purpose of selling the business as a going concern, he agreed to continue the business at an inclusive reduced rental of £2 12s. 6d. a week, on their promise to pay him one-half of any sum obtained for the business in excess of £125. On March 3 he was requested to vacate the premises, which he did, and was thereupon served with a default summons for £65 9s. 7d. claimed to be due in respect of rent and materials. Since that date he has traded only at the Balham premises. On March 18, 1919, he was summoned for non-payment of rates, £30 due in respect of the Balham shop, and filed his petition in order to avoid further proceedings.

The estate was left in the hands of the Official Receiver.

News and Notes.

LANCASHIRE SOCIETY OF MASTER PHOTOGRAPHERS.—An exhibition of work by members of the Society will be held in the Art Gallery, Blackpool, from May 27 to 30 next, both days inclusive. The exhibition will thus be open for inspection by members attending the annual general meeting of the Society, to be held in Blackpool, on Tuesday, May 27. It is hoped that members will contribute to making the exhibition a success by exhibiting at least three photographs each. All photographs submitted are to be mounted, on mounts not exceeding 20 by 16 inches in size. The entrance fee has been fixed at 7s. 6d. for each member competing and awards will be made by means of voting cards to be used by members of the Society. The latest day for the receipt of entry forms is Saturday, April 12. Forms and other particulars are obtainable from the Hon. Secretary, Mr. F. Read, 14, Balfour Road, Southport. A committee meeting of the Society will be held at the Chess Club, 65, Market Street, Manchester, on Tuesday, April 15, at 4 o'clock.

COLOURING AND FROSTING ELECTRIC BULBS.—The "Pharmaceutical Journal" gives the following formulae:—The varnishes for colouring electric light bulbs are usually made by dissolving sheet celluloid (2 to 3 per cent.) in amyl acetate, adding solution with a little methylated spirit, and then adding the desired aniline colouring. For producing a frosted or opaque effect, a sufficient quantity of light magnesia may be incorporated with the varnish; a very little quantity will suffice for the purpose. Or the frosting effect might be secured by first coating the bulbs with a solution of magnesium sulphate, 3; zinc sulphate, 3; dextrin, 2; in water, 20, drying thoroughly before immersing in or coating with the celluloid varnish. An American method of colouring is:—Make a solution by mixing the white of one egg, previously beaten to a froth, with one pint of distilled water. Filter, and skim the surface free from bubbles. The globes to be coloured are thoroughly cleaned and polished, then dipped in the liquid and hung up to dry. When dry, the dipping is repeated, and they are dried again thoroughly. The colouring solution is made by dissolving 10 to 30 grs. of any soluble aniline dye in 4 fl. oz. of collodion. In this the prepared globes are dipped and hung up to dry. The dipping is repeated if a darker tint is required.

A GRID FOR THE DARK-ROOM SINK

To the Editors.

Gentlemen.—On reading the article of "Practicus" in your issue of March 21, I notice that no mention is made of a kind of sink which I find most convenient. As perhaps it might be a useful suggestion for some of your readers, I will try and make as good a description of it as my imperfect knowledge of your language will let me.

The accommodation I use is a combination of board and sink. The actual sink occupies one whole side of the dark room. This sink which is lead-lined is about one metre (3ft. 3 ins.) broad and 30 cm. (12 ins.) deep. Two planks (about 20 cm., or 8 ins., high and 4 cm., or 1½ ins., thick) are set along both sides of the sink. Thinner planks, 4 cm., or 1½ ins., broad, are laid transversely on these, reserving a distance of two centimetres (¾ in.) between each, thus providing the board on which all the "wet" work can be done. The smaller planks are fixed on to the big ones by means of appropriate notches made in these. Thus the small transverse planks can be easily removed if necessary.

I find this accommodation to have the advantages of the usual plain sink (ability to pour solutions away, etc.) without having its inconveniences (bottom and sides of dishes, and consequently fingers of worker getting soiled by various solutions, which is a source of trouble).—Yours sincerely,

DENISE ARNU.

4, Avenue Percier, Paris 8, March 26.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed or reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

J. D. S.—Many thanks for your note; you will see that we are making use of it on another page.

M. L.—Ferrid-cyanide and ferricyanide are the same chemical. The former is now an almost obsolete word.

R. K.—You require to apply for particulars to the Secretary of New Business Licences, 27, Bute Street, Cardiff.

C. M.—The camera is made by Messrs. W. Butcher and Sons, Ltd., Camera House, Farringdon Avenue, London, E.C., who should be able to supply slides to fit.

MICHEL.—The only French journal at present published, and the one which now, as before the war, contains the greatest number of small advertisements is the "Photo-Revue," published at 118, Rue d'Assas, Paris.

DAYLIGHT.—If you write to the Vanguard Company, Maidenhead, they will send you a pamphlet, reprinted from the "British Journal," describing fully the making of firelight portraits, according to the method published by the late Mr. Essenhigh Corke.

L. B.—The "Howellite" lamp for studio portraiture is supplied by Messrs. John J. Griffin and Sons, Kemble Street, Kingsway, W.C.2. The vignetter to which you refer is the "Bram," supplied by Messrs. Wahlbach Smith and Co., Ltd., 30, Chapel Street, Salford, Manchester.

GEORGE TAYLOR.—You do not need necessarily to take out a provisional patent, although it is very commonly done. You can if you prefer file the complete specification in the first instance. Probably many of the inventors who file provisional specifications have the intention of endeavouring to dispose of the invention before the costs of complete protection fall upon them.

SKETCH.—Evidently your trouble is due to insufficient illumination of the background. You do not say whether they are made by day or artificial light, but we should judge the latter. In any case, you require to place the sitter well in advance of the background, so as to allow you to get a strong illumination on the latter whilst screening the sitter, if necessary, with a movable head-screen.

H. W. S.—The objection to using a half-plate lens on a quarter-plate camera is that in many instances you cannot get sufficiently far away from the subject in order to include the whole of it with a lens which will be about double the average focal length for a quarter-plate. For the greater part of the negatives which will be made with a quarter-plate camera, the most suitable focus of lens is from $5\frac{1}{2}$ ins. to 6 ins.

W. L.—If the portraits are on glass, they are collodion positives, and not Daguerreotypes. We should not imagine that they are original portraits of Queen Victoria and Prince Albert, but probably copies from some other photograph or painting, in which case their value is practically nil. On the other hand, if they should happen to be original portraits, the value should be considerable, although we have no means of judging what it should be.

SPARKBROOK.—You need a long-focus lens for obtaining satisfactory photographs of motor-cars; in fact, you can scarcely have one of too great a focal-length. For whole-plate negatives we should not hesitate to choose one of 30 or 40 inches focus. For half-plate negatives, a very good choice would be the 17-in. Telecentric, requiring a back focus of only 9-inches; or the Grandac Adon, which gives focal lengths from 25 to 50 inches.

S. H.—Photo-button plates are difficult to get now, as they come almost entirely from America, and importation is prohibited. If you cannot get from Messrs. Fallowfield, you probably cannot get them at all. We do not know a formulae for the developer.

The police in many districts insist on a hawkler's licence. You have to get a new one in each police district. In some cases they will not require it—in others we know that they do.

B. E.—We do not know of any more satisfactory method than that of bleaching with a mixed solution of potass. ferricyanide and ammonium bromide, and darkening with soda sulphide. Any of the alternatives, such as the permanganate bleach bath or a bleach of bichromate and acid, are more troublesome in use, and have no compensating advantages that we know of. Presumably the irregularities arise either from the chemicals, the method of making them up, or from variations in the paper.

DAZZLE.—The formula for the persulphate reducer of Mr. H. W. Bennett is as follows:—

Ammonium persulphate	480 grs.
Soda sulphite	96 grs.
Sulphuric acid	48 minims.
Water	10 ozs.

This stock solution is mixed with nine times its bulk of water for use. We believe the solution can be kept for a very considerable time.

A. D.—We do not think the markings arise from the ferrotype plates. As regards the water supply, the only possible way in which it can produce markings is through it being highly aerated, as, for example, being drawn from a tap at high pressure and the prints soaked in it immediately before laying down. But this cause is certainly unlikely. You could make yourself sure upon the point by soaking the prints in water which has been freshly boiled, and allowed to cool. We have met these markings infrequently, and, so far as we are able to ascertain, the cause has lain in the paper itself.

Line Advertisements.

Charges for Insertion.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind the scale of charges. They will thus save themselves delay in the publication of their announcements. A Schedule by which an advertisement can be correctly priced will be sent on request.

Net Prepaid Line Advertisements.

12 words or less	1/-
Extra words	1d. per word.
(No reduction for a series.)	

Special Note. Box Number Advertisements.

"Box No." and office address charged as 6 words.
For forwarding replies add 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.
Orders to repeat an advertisement must be accompanied by the advertisement as previously printed.

Advertisements are not accepted over the telephone or by telegram.
The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.

Displayed Adv'ts should reach the Publishers on Monday morning.
The insertion of an advertisement in any definite issue cannot be guaranteed.

SUMMARY.

In consequence of the Easter holidays, advertisements to appear in the "British Journal" of April 18 require to reach our publishers not later than noon on Tuesday, April 15.

We regret to record the death on Friday last of the eminent chemist and physicist, Sir William Crookes, at one time, for a short period, editor of the "British Journal of Photography" and of the "Photographic News." (P. 189.)

M. Auguste Lumière has recently carried out experiments showing the variations in the definition of X-ray photographs which may result from the construction of the tube, and from the conditions under which it is used. The tests show that tubes vary greatly in their capacity for sharp definition, and that their quality in this respect also undergoes relatively small modifications according to the time during which current is passed through them and to the degree of vacuum. (P. 183.)

A comparison of the efficiency of fluorescent screens in making X-ray photographs is contained in the abstract of a paper from the Eastman Research Laboratory. (P. 191.)

In a contributed article Mr. James Graham describes the making of lithographic transfers from bromide prints by a modification of the Bromoil process. (P. 188.)

In his article this week "Practicus" deals with the construction of a studio which can be erected in such fashion that, if need be, it can be removed and re-erected elsewhere. (P. 186.)

The small current of trade in German cameras continues. We deal in a leading article with the somewhat unintelligent comments upon the matter made by a London evening newspaper. (P. 182.)

A contribution to "Nature" gives a very encouraging account of the progress made by British makers of optical glass. It is stated that the full range of Jena glasses is now obtainable from British firms. (P. 189.)

The British Photographic Research Association has published a brief memorandum outlining the fields of pure and applied research which are included within its scope. Laboratories are now equipped for the research work of the Association. (P. 190.)

A contributor to "Assistants' Notes" deals with the practical measures necessary in the development and printing of amateurs' films. (P. 191.)

An undue deposit of fog in a negative may greatly mislead as to its printing quality. In a paragraph on page 181 we draw attention to a few of the more common causes of fog, some of which, particularly those arising from the camera, are often unsuspected.

The many practical advantages of rolled over ground glass for the glazing of certain parts of the studio are the subject of a paragraph on page 182.

EX CATHEDRA.

Organic Intensifiers. Many as are the processes which have been evolved by the ingenuity of the chemical experimenter, it cannot be said that we yet have a perfect process of intensification, speedy in use, performed in one operation, and thus capable of being stopped at the required stage and permanent in its results. Hitherto, with one exception, all intensifiers have been based upon the use of mineral or inorganic compounds, such as the metallic salts which exert an oxidising action upon the silver deposit, and thus, in one way or another, allow of an increase of density. The exception to which we refer—the single example of an organic intensifier—is that invented some eight or nine years ago by MM. Lumière, in which the oxidising agent is a quinone compound. The departure thus made into the infinitely wide field of organic chemistry is one which has not been followed, although there is every probability that among the many compounds and series of compounds of carbon which exist there are some in which the two properties of oxidising the silver image and of adding density when so doing are united. Now that the demands of photography, in the matter of developers, are becoming familiar to makers of organic products and intermediates in this country it may happen that the sister process of intensification may come in for a share of attention, even though the commercial rewards may be small in comparison with those yielded by a developer.

The Density of Negative Fog. The old idea that a negative must have a certain amount of clear glass is held by few printers now, but it is an undoubted fact that with a negative that is at all inclined to be on the thin side a very slight amount of fog reduces the printing value in a marked degree. It also gives a false impression of the real contrast present and prevents proper judgment of exposure when bromide or other development papers are used. It is an instructive experiment to reduce with ferricyanide and hypo one half of a foggy negative until the shadows are fairly clear, when it will usually be found that although the image, plus fog, appears fairly vigorous, yet, minus fog, it is really quite weak. It is therefore evident, when a negative clouds over in development more than it should do, that the development should be prolonged until considerable density is obtained; then when the fog is removed what is practically a normal negative will be left. If any one suffers from this class of negative, it is advisable that all precautions should be taken to avoid all possible causes of veiling. A very common one is diffused light in the camera; this may be through insufficient shading of the lens, to a dusty or cloudy condition of the glasses, or even to reflection from

imperfect blacking of the bellows or woodwork. It is a curious fact that in the wet collodion era, when there was much less liability to fogging, photographers were very careful as to shading the lens with long hoods, cones, or canopies, while now we may find people using rapid anastigmats with half-inch hoods or none at all, and this with ultra-rapid plates. The point should receive especial attention at the hands of those who go in for "fancy" lighting, with the lens pointing more or less directly to the light. With dirty lenses the remedy is obvious: a little alcohol and a soft rag are all that is needed, although a coating of dead black or even black velvet inside the lens tube, is a valuable addition, while treatment with a really dead blacking such as nigrogene on the bellows and framework should complete the cure. If the fogging occurs in the camera the edges of the plate where protected by the rebate should be clear, otherwise the cause must be sought in the dark-room. Coloured fabrics fade and some red glasses permit a considerable proportion of blue light to pass through. It is worth taking a little trouble in tracing the cause of fog in order to secure clean, easily printed negatives.

* * *

Glass for the Studio.

A correspondent recently asked whether the use of rolled or ground glass for glazing the studio would obviate the necessity for white blinds or curtains in addition to dark ones. In our opinion, in an at all well-lighted position it would not do so, as although either kind would prevent the direct glare which sometimes comes through clear glass, there would be no effective control of the light. There is, however, much to be said in favour of what is generally called "rolled plate" for both roof and sidelights. For one thing, it effectually excludes all view from the outside, even when using artificial light, while another advantage is that the light is more evenly distributed about the studio, with the result that the shadows are less intense, and the exposures shortened in spite of a certain proportion of the light being absorbed. If the glass is neglected dust and dirt will accumulate in the ribs and cause considerable waste of light, but an occasional wash with soap and water, applied with a soft brush, will remedy this. Of ground glass we cannot speak so well. It certainly diffuses the light and is, therefore, useful where there are outside obstructions, for it is well known that a side light of ground glass will give better illumination if there is a wall near than clear glass will. On the other hand, it rapidly gets yellow in a smoky atmosphere, and it is then more difficult to clean than the rolled plate. Moreover, as it diffuses the light more than rolled or clear glass, it is more difficult to get decided effects in lighting with it.

* * *

Defects in Sketch Portraits.

Few photographers pay sufficient attention to the lighting of the sitter when producing negatives for sketch portraiture, and many examples that we have seen in professional show-cases point to negligence in this respect. The charm of a good sketch portrait, in our opinion, lies in its fine tonal quality and delicacy, while if an over-harsh or too unequal lighting is arranged a very inferior effect is obtained. One of the best sketch portraits that we have seen was made with a decidedly flat lighting, but one that, at the same time, by the aid of first-class photography, was a delightful result of tonal quality and colour suggestiveness. While on the subject, a word may be added with reference to the sitter's costume. In the case of feminine sitters, the sketch portrait should always be in a high key, and, if possible, the receptionist should advise light clothing free from any trace of dark. We recently saw a bust sketch portrait of a feminine sitter in a high key that was abso-

lutely ruined from the artistic point of view by the inclusion of a dark tie. The removal of this should have been tactfully suggested by the photographer. Many child-portrait sketch effects in a high key are considerably reduced in artistic value through a dark-coloured hair ribbon, and we have before us a delightful full-length sketch portrait of a youthful sitter in a light dress completely spoilt by reason of the fact that the sitter is wearing dark socks, or, perhaps, those of a colour that photographed too dark, if a non-ortho plate was employed. The above are some points that have a real bearing upon success and should be noted by all sketch portrait workers.

THE TRADE IN GERMAN CAMERAS.

SINCE the appearance of our note in the "British Journal" of March 28 last this unpleasant subject of the trade which is now going on in German cameras has cropped up in one way or another somewhat freely in the daily Press. For example, we have noticed two German cameras advertised for sale in the "Personal" column of the "Times." Both were described as new, and in one case the complete set, comprising a focal-plane camera of a type little sold in this country before the war, a well-known objective, and three double dark-slides, was offered at £24. Curiously enough a correspondent drew our attention to a new German camera at this same price being displayed in a London dealer's shop window. It is therefore evident that the trade is still going on and is passing, not merely through the channels of the lay Press, but also of the dealers' establishments.

A paragraph in the "Daily News" takes us to the source of this illicit trade. The writer quotes from a circular which, he states, is being distributed in the streets of Cologne. On the outside page is printed in big type, "Now's your chance. You will never get a good German camera as cheap again." On the inside pages of the circular are stated the name and address of the firm of dealers and the names of the photographic makers—the four best known in Germany—whose goods are obtainable. A characteristic touch is provided by the announcement in the largest type, "English spoken."

But the most remarkable contribution to this matter which we have met in the lay Press is contained in the London letter of the "Westminster Gazette" of April 2. The writer makes the most extraordinary deductions from the fact that a camera can now be bought in Cologne for about £6, which in pre-war times would have cost £13. According to him, the subsequent appearance of these cheaply bought cameras on the English market seriously disturbs the second-hand dealers here from the fear of the value of German-made lenses and cameras held by them being depreciated. If the writer had taken the trouble to find out he would have discovered that the volume of trade which has arisen since the armistice is altogether too insignificant to have the result he suggests. Certainly the dealers are disturbed—disturbed by the fact that the necessity of taking steps to put a stop to this trading with the enemy should be imposed upon them as a consequence of official apathy in taking the matter in hand. The Photographic Dealers' Association in a letter addressed to the "Westminster Gazette" by the President, Mr. James A. Sinclair, and appearing in the issue of the 10th inst., points out that in most instances dealers are refusing to deal in apparatus which has been made since the war commenced, and which is now reaching this country through the purchases of soldiers in the army of occupation, although the purchase and re-sale of these new cameras would be very profitable to them. But the writer in the "Westminster" is apparently obsessed with the idea that by some means or other

photographic dealers have during the war maintained the prices of second-hand German-made cameras at a highly profitable level, and is thus led to impute their desire to exclude the new instruments merely to motives of self interest. It would be interesting to know along what line of reasoning the writer eliminates the public from this conclusion. Let the dealer price his second-hand German cameras as high as he likes, or, for that matter, as low as he likes, they would stay on his shelves unless the public bought them. In matters of tariff reform writers in the "Westminster" are eager to lay emphasis on the laws of supply and demand on which obviously the sale of the goods in question solely depends. When war broke out there must have been very considerable stocks of German cameras distributed throughout the second-hand trade. Clearly no stigma could attach to dealing in them, and if, as we have said, the public has been willing to pay highly for them the dealers have been entitled to their profit. The writer in the "Westminster Gazette" now suggests that dealers "should have done with this trade" in order that they may avoid suspicion of selling new German cameras now coming into the country. Surely a drastic enough remedy for a state of things which has been none of the seeking of dealers in this country.

The only remedy for the present difficulty is that the bringing of these goods into the country should be prohibited. The leading dealers have no doubt set their faces against trading in the goods, but unless all are solidly united in this policy there will obviously be the induc-

ment to every one of them to take part in it from the knowledge that if he does not purchase the goods somebody else will. Moreover, there are the channels of the auction room and advertisement in the lay Press. We believe that representations have been made to the Ministers concerned, but very little may be expected from those quarters. It may, therefore, be hoped that the whole influence of the Photographic Dealers' Association will be thrown on the side of reducing the market for these cameras. Probably the most effective means of this kind would be the publication of a list of dealers refusing to purchase any cameras which they have reasonable ground for assuming to be of recent importation. A restriction of market would have its reacting effect upon prices, and would thus apply the most effective discouragement to the bringing of these goods to London for sale.

In conclusion, while we are upon the subject, we should not refrain from reference to a message by Renter's Special Service from Cologne which appeared in the "Daily Telegraph" of March 31 last. Dealing with the wider opening of the door to trade between Germany and the occupied zone, and discussing also the resumption of trading relations between Germany and Great Britain as a means of Germany paying her share of war expenses, the writer singles out "camera parts, lenses, etc.," as goods which England "is ready enough to receive." It would be interesting to know what grounds Renter's correspondent has for making a statement which every evidence goes to show is the very antithesis of the facts.

DEFINITION IN X-RAY PHOTOGRAPHS.

A Paper from the "Revue de Radiologie et d'Electrologie."

THE images formed in X-ray photographs are produced, as is well known, from conical projections; they are the shadows thrown on a screen or photographic plate of objects of various degrees of permeability to the rays emitted from the X-ray tube and travelling in straight lines. Were the ray-source simply a point, the images would be of a high order of sharpness, and their size would vary simply according to the relative distances of the ray-source, the object, and the screen, diffraction phenomena which tend to distort the forms of shadows in the case of luminous rays not taking part to any appreciable extent in X-ray phenomena. But, in fact, the radiation is emitted not from a point, but from a surface the size of which can vary not only according to the tube which is employed, but also for a given tube according to certain conditions of its action.

In the use of a tube the bundle of radiations which is emitted appears to proceed from the centre of the anti-cathode from an area which is commonly called the "point of impact," but which, for practical purposes, is a surface of some area. Independently of this principal bundle, the passage of current in the tube gives rise to the emission of secondary radiations, which have their origin in the neighbourhood of the surface of impact at the level of the whole anti-cathode. Also the portion of the tube which is illuminated itself emits a certain radiation. These subsidiary radiant sources possess dimensions which are large relatively to that of the surface of impact. They cannot give rise to well-defined shadows, on account of their extended area, but their relative intensity is fortunately very small, and the influence which they exert upon the definition of X-ray images is of small degree. Their effect consists in the addition to the principal image of a species of general veil or fog, which reduces contrasts without

modifying to any appreciable extent the definition proper. The object traversed by the X-rays diffuses in its turn other supplementary radiations, the injurious action of which is additional to that of those already mentioned. In the present study these secondary rays are not considered, the object being to investigate only the causes capable of modifying the surface of impact, which is the chief ray source. The experimental

arrangement which was used is the following: On a sheet of thin card, E, F, four rectangular spaces, A, B, C, D, were filled with wire gauze of various degrees of fineness represented by 11, 20, 36, and 44 threads per cm. These are the ordinary commercial metal gauzes. This test piece is arranged on a frame open at the bottom, as shown in the drawing, and of size to place the set of gauzes 10 cm. (=4 inches) from the sensitive surface.

The anti-cathode being placed at 50 cm. (= 20 inches) from the plane of the plate, a series of tests were made by working under normal conditions, which were kept as constant as possible, and by using different tubes. The negatives obtained were enlarged two and a-half times, in order better to display

the definition obtained. It is first to be noted that in normal use all the tubes do not give the same results. The images reproduced show that the definition varies with the different tubes. With a certain tube, A (Fig. 1), the four gauzes are visible; with another tube, B (Fig. 2), the structure of the test-piece can still be recognised, though less sharply, whilst with a third tube, C (Fig. 3), three of the gauzes out of four are visible, and two only out of the four when using a tube, D

slightly modified—that is to say, appreciably extended—during the operation of the tube. Tests made in the same way with other tubes exhibited the same differences.

It therefore seemed desirable to discover if the surface of impact is displaced during the passage of current in the tube, and for that purpose, using the same arrangement as in the preceding experiment, plates were exposed for the same time (three minutes), but dividing this period of exposure into three

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

(Fig. 4). In another case (tube E) only the gauze of large mesh is recognisable (Fig. 5). Lastly, deformation of the images is sometimes encountered, indicating a surface of irregular impact (Tube F, Fig. 6).

It may be asked if these differences, which are often considerable in comparing one tube with another, arise from the construction of the tube or from the conditions in which it is used. It therefore seemed advisable to discover if, during the use of the tube, the surface of impact sustained displacement or deformation capable of modifying the definition of the

parts, each of one minute, the first corresponding with the beginning of the period of the tube's action, the second with the mid portion, and the third with the end. There were thus obtained images the definition of which was slightly inferior to that obtained by a single exposure of three minutes at the end of the period of action. It therefore appears that the surface of impact undergoes slight displacement in the course of the operation of a tube for several minutes. Moreover, this result appeared to be confirmed by the comparison of two tests made with the same tube, one with an exposure of 1-100th second

Fig. 5.

Fig. 6.

Fig. 7.

Fig. 8.

images; and in the same connection the influence of current intensity and of the hardness and age of the tube were studied. In making these tests the tube A, which in a preliminary trial had yielded the most distinct image of the four gauzes, was first used. An impression was made of the test-piece at the beginning of the period of operating the tube, and then after an interval of two minutes a second image was made with the same time of exposure, at the end of the period of action. The first image is a little sharper than that obtained after the two minutes: the same test was repeated after allowing the tube to remain in action for six minutes, and gave practically the same result, represented by Fig. 6. Thus the surface of impact is

by means of a "flash" apparatus and the other of 5 seconds. The instantaneous image is a little better defined than the other, but in this experiment several conditions had been necessarily modified at the same time, and it is scarcely possible to draw definite conclusions from it. The comparative images are reproduced in Figs. 9 and 10.

The second question which has been examined relates to the modifications in the radiant surface consequent upon variation in the intensity of the current which passes through the tube. Precautions were taken to maintain the working conditions as constant as possible, and the definitions of images afforded by a given tube were compared in the different circumstances of

passage of a current at different intensities, in one case one-quarter of a milli-ampère and in another of 15 milli-ampères. These tests were repeated with different tubes, and the results invariably showed that differences in intensity do not appear to exert any appreciable influence upon the definition. The results are so similar that it is not necessary to reproduce them.

It is, however, different when the degree of vacuum of the

the third gauze. It should be understood that the question which is here discussed is the defining power of the tube quite apart from the contrast in the image—two qualities which frequently are confounded. It is evident that the tube A of maximum hardness, and having a spark equivalent of 20 or 25 cms., will never distinguish tissues which are relatively permeable by X-rays. e.g., it failed to disclose stone in the kidney, though it rendered the four gauzes excellently, whilst

Fig 9

Fig 10

Fig 11

Fig 12

tube is varied. Using a hard tube, with a spark equivalent of 18 cms., a plate was exposed and the spark equivalent then reduced to 3 cms., a second plate being then exposed. The results were better in the case of the hard tube, but on repeating the same experiment with other tubes the results were no longer the same. It would appear that for a given tube there is a degree of hardness which corresponds with the maximum definition. The convergence of the cathodal rays thus appears to undergo variations according to the degree of

the tube D did not suffice to yield definition of the two finer gauzes, however the conditions of its use were adjusted, but was perfectly able to yield satisfactory images of renal calculus when the precaution was taken to bring the tube to a suitable degree of exhaustion. Thus, from the point of view of definition each tube has its own characteristic properties, which are but slightly modified by the conditions of its use.

In the course of the experiments confirmation was obtained of the known fact that the definition of X-ray photographs

Fig 13

Fig 14

Fig 15

Fig 16

vacuum, but these modifications, as shown in Figs. 11, 12, 13, and 14 are not of great importance. The figures show the extreme range of definition which it was possible to obtain in the course of the tests with a given tube. Thus, even when departing to a notable extent from the customary conditions of radiographic practice by varying within abnormal limits the exhaustion of the tube and its time of action, the differences in the definition are only trifling. The tube which allowed of recognising the four gauzes in the first test made under average conditions invariably rendered the test-piece, however the conditions of use were changed, whilst with the tube D it was never possible, by any modification, to obtain a rendering of

increases in proportion as the distance of the anode from the plate. Using the same tube, placed successively at 30, 50, 100, and 150 cms. from the plate, and giving exposures inversely proportional to the squares of these distances, four plates were exposed and yielded images which show the improvement in definition which results from a more remote position of the tube. The figures are 15, 16, 17, and 18 respectively. The results are mentioned here in order to show the degree of importance of the distance of the tube in X-ray work. Since want of definition in X-ray photographs appears to result from the fact that the ray source is not a point but an area throughout the whole of which rays are emitted, it

seemed that improvement should be effected in a certain measure by inclining the tube so that the anti-cathode is placed in a plane almost perpendicular to the surface of the plate. By thus working at the limit of the field, the surface of impact is presented almost perpendicularly to the plane of the plate, and thus becomes practically a line ray-source. If the suppo-

son with the Coolidge tube, but it may be concluded from the experiments which have been made that improvement in the definition of X-ray photographs is a question of reducing the area of the surface of impact. The solution of this problem, which is beyond the scope of the present paper, but which it is hoped to discuss in a later communication, is not the only

Fig. 17.

Fig. 18.

Fig. 19.

Fig. 20.

sition is correct the rays from this line-source should give exceedingly sharp shadows of lines of the gauze parallel to it. Such was found to be the case, as is shown by the two comparative images of Figs. 19 and 20.

All the tests were made with the tubes of Pilon, Muller, and Radiologie. It is proposed to carry out further compari-

desideratum which may contribute to the improvement of radiographs, sharp definition being only one of the elements in the question. In addition, there are to be considered the defects introduced by secondary rays, and the influence of these latter is the subject of current investigation.

AUGUSTE LUMIÈRE.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
The Camera and the Lens (Jan. 10).
Managing the Sitter (Jan. 17).
Backgrounds (Jan. 24).
Studio Exposures (Jan. 31).
Artificial Lighting (Feb. 7).
Printing Processes for Portraiture (Feb. 14).

Studio Accessories and Furniture (Feb. 21).
The Surroundings of the Studio (Feb. 28).
Studio Heating and Ventilation (March 7).
The Postcard Studio (March 14).
The Printing-Room (March 21).
About the Reception Room (March 28).
Home Portraiture (April 4).

PORTABLE STUDIOS.

THE term "portable" has a wide range of meaning when applied to a photographic studio. It may mean a caravan on wheels, a wooden building which can easily be taken to pieces and erected elsewhere, a specially designed tent, or even a temporary shelter for the sitter and background, the camera and operator being in the open.

Studios in the first category—that is to say, of the caravan type—are now not so common as they used to be in the early collodion days, when many villages, and even small towns, had no photographer domiciled in them. There are, I believe, some which travel along with roundabouts, wild beasts, and fat ladies from fair to fair throughout the country, but I have not seen one for a good many years. Some of them were quite elaborate affairs, fitted up not only for glass positive and ferro-type work, but for printing on albumenised paper, the work often comparing favourably with that issued by many fixed studios. It may puzzle those who have never seen one to imagine how sufficient space was obtained, but this was easily

done by adopting a telescopic form of construction, an inner body sliding out and being supported upon trestles.

The term which will probably be of most interest to the majority of my readers is not a studio that is here to-day and gone to-morrow, but one which is intended to remain in one place for months, if not for years, but which can, if needed, be removed and re-erected at small cost, and by unskilled labour. Such studios are usually made entirely of wood and glass, and their portability is due to the fact that there is no general framework, but that the whole is built up in panels, which are fastened together with ordinary iron bolts and nuts. I will endeavour to give some idea of their construction, which is quite simple and well within the powers of the village carpenter, or even of an amateur who has some idea of wood-working. The first thing to be decided upon is the size, and, this being done, a drawing should be made and the size of the panels settled. It is necessary to be very careful in constructing these that they should be exactly the size that they

are supposed to be, or there will be a lot of unnecessary work when it comes to fitting together. The design is usually the ridge-roof one, somewhat after the pattern of Noah's ark without the barge. For a studio 20 x 12 by 8 ft. (to the eaves) and 11 ft. to the ridge the following divisions will be convenient:—Each end is in two sections 6 ft. wide, one side being 8 ft. long and the other 11 ft. long. The two pairs of panels are exactly alike, except that one will probably have the door frame fitted into it. It must not be forgotten to keep the frames on the proper sides when nailing on the boarding, or they will have to be remade. I mention this because I have known three right-hand sections and one left-hand made, instead of two of each. The sides are made in four sections, each 5 ft. wide and 8 ft. high. Six of these are entirely covered with wood, and two have a cross-bar, say, 4 ft. up. Below this, wood is nailed on; above are sash-bars for the side-light. The roof calls also for six wooden panels and two which are frames only, fitted with sash-bars for the top light. These are all 5 ft. wide and about 7 ft. long, so as to give a slight overhang at the eaves. The edges which meet at the ridge should be bevelled so as to give a good bearing. For a studio of this size the frames of the panels should be made of 4 x 3 deal, and the boarding should be good yellow $\frac{3}{4}$ matching. The frames may be mortised if the extra labour is not objected to, but "halved" joints answer quite well, as the boarding has to do its part in keeping the panels square; good cut nails should be used for fastening. The side and end panels should each have a crossbar half-way up, as not only does this stiffen the construction, but it keeps the boarding from warping. In all the panels the framing comes inside the studio, and the panels are fastened together by drilling holes in which the bolts fit well, and without shake in the frames, so that, when laid side by side, they are drawn closely together. In the end sections the bolts run through the boarding as well as the frame, and are tightened up in the same way as the side joints. It is perhaps hardly necessary to say that the woodwork should all be erected before the glass is put in the sashes, and that, in case of removal, the glass should be taken out before anything else is done.

Having made all our panels, we can assemble them. First the two ends are put together, and then the sides joined up to their full length. The back should next be joined to the ends, then the front fixed in, and finally the roof sections put up in pairs and screwed through on to the tops of the frames. Although not always done, it is a good plan to put one or more iron tie rods across at the level of the eaves to prevent any outward thrust. These should be $\frac{3}{4}$ in. to 1 in. in diameter, threaded at the ends with a good large nut put on both sides of the top of the side frames through which the rod goes.

The flooring is made in panels the width of the studio, and drops upon the lower part of the frame. There should be some arrangement of joists or brick piers to prevent vibration and sagging.

The roof will require a waterproof covering. This may be corrugated iron or the asphalt roofing material known as Ruberoid, or, if obtainable, Uralite, which is fireproof, may be used. This is a sort of asbestos and plaster composition, and would keep the studio cooler than iron. It has the merits of not rusting and requiring no paint.

A building erected in the above way will not keep in condition long if placed directly upon the ground; therefore, some foundation which will keep the lower part dry must be provided. For a reason to be presently given this should be of a temporary character, and one which we found very successful was a row of loose bricks all round, the exact size of the studio, with two rows at equal distances running from end to end inside. Upon these bricks rested four long deals 20 ft. long and 3 x 9 section; the sides of the studio stood upon this, and there was sufficient space between the bricks for air to circulate freely below. A studio so erected was taken

down after nine years, and was found to be quite sound, as were also the long timbers.

If one is building upon another person's land it is necessary to be very careful to do nothing that will give the landlord a claim to the building. If a studio or greenhouse is erected upon a brick foundation which forms an integral part of it, the whole at once comes under the control of the landlord, and the tenant cannot legally remove it. It has been held in the case of a lean-to greenhouse that the driving of iron holdfasts into the wall of a dwelling-house to secure part of the framework removed the structure from the category of "tenant's fixtures," and made it a part of the freehold.

The foregoing description is necessarily of a sketchy nature, but I shall be pleased to fill in any details in the "Answers to Correspondents" column in case of need.

Tent studios are not much in favour in this country, as there is no possibility of using glass as part of the covering, and there is no waterproof material which will retain its whiteness for any appreciable period. Celluloid is, of course, out of the question, on account of its cost and inflammability. The most elaborate tent studio I have seen was one sold by the Stereoscopic Company a quarter of a century ago. It consisted of a wooden skeleton of the ordinary ridge-roof form. The parts usually solid in a permanent studio were covered with tightly stretched sail canvas; the top and side lights were without any permanent covering, and were fitted with dark and light roller blinds of the usual type. This was necessarily a rather costly affair, and a much simpler arrangement could be constructed with an ordinary small marquee as a basis. If an opening were cut in a suitable position and a light wooden frame, or frames, fitted with wires and festoon blinds put in, quite a useful studio could be made. Some years ago a woven wire roofing, the meshes being filled with a transparent varnish, was placed upon the market; it was tried for studio lighting, but, being rather yellow, caused the exposures to be too long. Now that plates are three times as fast it might be worth trying it again, if it is still made. I have often thought that a serviceable studio might be made upon what is known as the tunnel principle—that is to say, a comparatively short square compartment for the sitter and background and a small tunnel or passage without light for the camera and operator. This idea could be worked out in the form of a tent, and would have the great advantage of being economical of material and presenting the minimum area to wind pressure. It would not be difficult to arrange such a studio so that an ordinary shower need not interrupt work.

So-called "lawn" studios are merely devices for holding a background and curtains for cutting off the waist of the top and side light. Houghton's used to list a very neat arrangement of this type. It is, however, very easy to improvise something of the sort with four tent-poles and cords, a background, and some lengths of light and dark materials for curtains. All that has to be done is to fix the four poles at the corners of an 8 ft., or smaller, square, to run a cord round the tops, steady the whole with the ordinary ropes and pegs, and hang the background on whichever side suits the light. The lengths of material are hung over the top cord to serve as studio curtains. One friend of mine had four clothes post sockets fixed in his garden at the proper distances for a studio of this sort, and could drop the posts in, rig up the curtains, and get to work in less than ten minutes.

PRACTICAL.

A STOLEN GOERZ LENS.—Messrs. Boyde's Studios Limited, 108, Strand, London, W.C.2, advise us that a 1B Goerz Color lens of 180 mm. focus, $f/4$ aperture, iris diaphragm and numbered 145169 was stolen from their premises on March 28 or 29 last. They will be grateful if anyone to whom the lens may be offered will communicate with them.

LITHOGRAPHIC TRANSFERS FROM BROMIDE PRINTS.

THE Bromoil process has for several years had an important application in the lithographic trades as a means of readily making enlarged or reduced productions of line or "stipple" copies. The method also lends itself to the production of coarse-grained half-tone lithographs. In this process a negative is made from the original line or tone drawing, or from an existing reproduction. From this a bromide print is made of the size required, which is subsequently treated by a modified Bromoil process so as to become transformed into a lithographic transfer.

Details are given below of a method which has been produced after numerous experiments. These were undertaken by the writer with a view to obtain general reliability and ease in results.

Character of the Negative.

The negative may be made either on a dry plate or by the wet collodion process. It must be quite sharp. Line negatives should be made with a fairly large stop, or there will be a slight diffusion of detail in the finer lines. This is due to the fact that the anastigmat lenses generally in use are designed primarily to work at large apertures. $f/16$ to $f/22$ is about the correct stop to use. Half-tone negatives must have the dot formation well joined in the high-lights. The particular screen to use for half-tone work must be calculated. For example, if the print from the negative is to be enlarged two diameters and a 75 lines per inch grain is required, the negative must be made with a 150-line screen.

Making the Print.

The ordinary copying camera may be used for making the print, the negative being rigged up a foot or so in front of the copy board, which is covered with white paper, so as to reflect light through the negative. A better way, when work is to be done in quantities, is to use an enlarging lantern. Whichever method is adopted, care must be taken to focus quite sharp, and again to use a fairly large stop.

The most suitable developer is the regular amidol or diamidophenol formula, using plenty of bromide. The fixing bath must consist of plain hypo and water, and nothing more. Exposure should be just long enough to produce a full strength deposit in the finest lines. Development should be full. After fixing the print it should be washed for not less than ten minutes, and then dried.

Making the Transfer.

The print, when dry, is ready for bleaching. This should be done by means of the following bath:—

A. Copper bichloride	60 grs.	5 gms.
Ammonium chloride	240 grs.	20 gms.
Hydrochloric acid, about ...	20 drops	2 c.c.s.
Water	10 ozs.	400 c.c.s.
B. Sodium bichromate	12 grs.	1 gm.
Water	2½ ozs.	100 c.c.s.

For use take 2 ozs. (50 c.c.s.) A., ¼ oz. (6 c.c.s.) B., and 4 ozs. (100 c.c.s.) water.

The print should be fully bleached in about two minutes. Occasionally a strong print will fail to bleach right out. The partly bleached portions will, however, take the ink quite well. After bleaching, the print is washed for not less than four minutes in running water.

While the print is washing the inking slab should be got ready. Take a little re-transfer ink on the end of a palette knife and rub it out on an old litho stone, or other suitable slab, thinning it down with xylol or benzole. Turpentine is unsuitable for this process.

The washed print is now blotted off, and laid on a sheet of zinc or glass. Take a fairly tough letterpress roller, or better, a rubber-covered roller, and distribute the ink all over the inking slab, diluting with xylol until the roller has a tendency to skid over the surface of the slab. Now roll up the print with the roller in this condition. At first the print assumes a uniform grey tinge, and then, as the xylol evaporates, the stiffening ink leaves the whites and adheres more and more to the bleached parts. In a

few seconds the maximum effect is reached and the rolling stopped.

The print should at this stage appear full of detail and of a greyish-black colour. There may be a very thin film of ink left upon the whites. In order to remove this, take a piece of thoroughly wet cotton wool and rub lightly over the print until clean. The transfer is then ready for the lithographer.

Weak Prints.

Sometimes a print is too weak in character for the bleaching solution to act with full effect. In this case it will be found that fine details do not ink up. Such a print may be saved by a re-development operation, as follows:—Clean all ink from the surface with a piece of cotton wool moistened with xylol, and then put it in an ordinary amidol developer, such as was used to make the print originally. It quickly blackens, and should be washed for four or five minutes, when it may be re-bleached in the Bromoil bleacher. No fixing is necessary before re-bleaching. The print will be found to have received an extra dose of hardening action, and will usually ink up well.

Inking up of the transfer by means of the Bromoil brush is favoured by some workers. It is useful at times for the purpose of bringing out portions of a print which may lack detail. In order to use a Bromoil brush some re-transfer ink must be mixed with a mere trace of boiled linseed oil and the tip of the brush charged with this, no xylol being used. The charged brush is dabbed upon the required parts of the print until sufficient ink has been taken up, and the inevitable dirtiness of the whites removed with wet cotton wool. The print can be persuaded to take up more and more ink by adding a greater proportion of boiled oil. As a rule, however, attempts at faking of prints are not to be recommended.

General Considerations.

Almost any grade of bromide paper can be used for bromoil transfers. The most suitable is a matt smooth paper, which is coated on a substantial base. It is well to be sure that the emulsion has a fine grain. Glossy paper gives bright-looking prints, which, however, the lithographer finds difficulty in transferring to stone or plate, owing to the extremely high relief.

Transfers may be re-inked and re-used a number of times, the limit being governed by the toughness of the paper base.

Some grades of paper have a tendency for the gelatine coating to strip off during inking. This tendency may be minimised by using the bleacher given above. Lack of strength hitherto has been, apparently, due to the softening of the baryta base on which the emulsion has been coated. By substituting ammonium chloride for the more usual sodium salt this defect is overcome. The object of hydrochloric acid in this formula is to enable ordinary tap water to be used. The acid neutralises any hardness in the water. Sodium bichromate was found to be the most reliable chromic salt to use.

Stretching of Transfers.

Sometimes it is important that the impression must be of exact size. In such cases the bromoil transfer process hitherto has been hardly feasible, owing to the tendency for the paper base to stretch unevenly. A bromide paper, known as Kerotype, has recently been placed on the market, which to a large extent overcomes this defect. It is a stripping paper—i.e., the prints are first made on a bromide emulsion which has been coated on an impermeable base. These prints are then soaked in a mixture of spirit and water, and the emulsion is transferred by means of a gelatine solution to a suitable support, such as celluloid.

JAMES GRAHAM.

Mr. W. T. FURNISS, of 21, Fargate, Sheffield, has been elected on the Sheffield (Ecclesall) Board of Guardians.

Mr. JOHN ELLIS, the well-known photographer of Malta, was recently awarded the French distinction of Palmes d'Officier d'Academie, in recognition of his services during the war.

RONTGEN SOCIETY.—The second Sirvanus Thompson Memorial Lecture will be delivered by Professor W. M. Bayliss, M.A., D.Sc., F.R.S., of the University College, London, on Tuesday, May 6, at 8 p.m., in the Barnes Hall of the Royal Society of Medicine, No. 1, Wimpole Street, London, W.1.

DEATH OF SIR WILLIAM CROOKES.

We regret to record the death on Friday last, April 4, in his eighty-seventh year, of Sir William Crookes, the eminent chemist and physicist.

The life work in scientific investigation of Sir William Crookes could easily require a whole issue of this Journal for its adequate statement. Inasmuch as lengthy notices of his work have appeared in the daily newspapers it will be sufficient for us to deal with his connection with photography, which was direct and in some respects notable. We have no means of discovering by what channel Crookes as a young scientific man was led to take a special interest in photographic processes, but it is to be borne in mind that in the fifties and 'sixties of the last century when photography was a comparatively new thing its advancement enlisted the interest of leading scientific investigators to a much greater degree than in later years. Thus, when twenty-two years of age, he was asso-

The late Sir William Crookes.

ciated with Mr. John Spiller in devising one of the many processes of that day, which had the object of producing a collodion plate which could be employed "dry," and so overcome the drawbacks attaching to the wet-collodion process invented by Scott Archer. The process of Crookes and Spiller consisted in bathing the iodised collodion plate as usual in the silver bath and then immersing it in one containing also a little nitrate of zinc. The latter kept the plate sufficiently moist for it to be preserved for a day or two without suffering in sensitiveness. For the benefit of present-day students of the past processes of photography let it be observed that the term "dry collodion," as applied to sensitive plates, is somewhat loosely employed. Probably more often than not the aim of experimenters was to obtain a plate which could be kept in a moist condition. Others, such as Dr. Hill Norris, succeeded in making plates which preserved their sensitiveness when quite dry, but this process may be said to be almost the only one which strictly corresponded to the generic title of dry collodion, which was applied to these developments of Scott Archer's invention. A contribution to photographic processes, which is commonly attributed to Crookes in the textbooks of the last century, is that of having been the first to use the light of burning magnesium for taking photographs. We cannot, however, trace this pioneer step in photography by artificial light to his original communication. The older literature contains also many contributions by Crookes in the field of the spectral sensitiveness of various silver compounds, but, after all, photography appears to have been purely a scientific hobby of his in his younger days, and, except that he constantly used it in his physical investigations, his active interest in it is confined to the comparatively early

days of the science. In January, 1857, Crookes became editor of what is now the "British Journal of Photography," but which was then issued as the "Liverpool and Manchester Photographic Journal." Apparently his editorship lasted for only about two years, and in 1859 he became the first editor of the "Photographic News" on the founding of this periodical by Messrs. Cassells. So far as can be traced from the published volumes he held this position only for two or three years. In the sphere of X-ray photography Crookes will always be remembered as having provided the means, in the Crookes' tube, for the production of the rays, whose properties were first recognised by Röntgen.

Sir William Crookes and Mr. John Spiller. From a collotype print of about the year 1855.

In reproducing a portrait, taken a few years before his death, we may supplement it by one taken about the year 1855, and including Crookes's early collaborator, Mr. John Spiller, almost the oldest of the early experimenters in photography who are still with us.

OPTICAL GLASS.

[A brief review of the history and process of manufacture of optical glass in "Nature" of March 22 last contains reference to the achievements of makers of optical glass in this country during the period of the war, which, from such a well-informed source, will be welcomed as conveying the assurance that opticians here will not be again dependent upon the German optical glass. We quote the portion of the article which specially refers to the glasses required for photographic lenses.—Eps. "H.E."]

The advent of dry plate photography and the special corrections desirable in camera lenses, as well as in microscope objectives, gave a great stimulus to the work of German investigators, and their researches, carried out with more perfect technical appliances, had a wider aim in view than those of the English experimenters. The results obtained were of such promise and importance that Government assistance was forthcoming in the setting up of works for the manufacture of new glasses on a commercial scale, and the joint-taking efforts of these men of science in overcoming the difficulties involved were eventually rewarded with well-deserved success.

As a result, opticians were compelled for many years to go to Germany for glasses having special properties such as were absolutely

necessary for them in the design of the better types of certain optical instruments. And, as many of the more important instruments during the latter part of last century were of German design, the firms concerned naturally transferred almost the whole of their orders from the English and French firms to Schott and Co., of Jena, and, in fact, so far as the military requirements of Germany were concerned, they were compelled to do so by the German Government.

It may be said, however, that the products of the English and French firms, as regards the older varieties of optical glass, were never surpassed by the Jena firm. This is evidenced by the fact that the English and French firms produced the great majority of the large discs for the giant astronomical refracting telescopes constructed during the last forty years. At the British Scientific Products Exhibition, recently held in London and Manchester, a fine disc of crown glass, 28 ins. in diameter, which was produced immediately before the war, was exhibited by Messrs. Chance Brothers.

The British firm, in particular, was slow in taking up the manufacture of the newer types of optical glass, and had to encounter serious disadvantages in coming late into the field in this respect, as also in being unable to obtain any Government assistance. The great value of the previous production of optical glass in this country, however, was felt at once on the outbreak of war, when Messrs. Chance Brothers were able to extend their resources, and, without outside assistance of any kind, to develop the manufacture of all the types of glass required by opticians, including some of the most extreme of the Jena varieties, which became necessary owing to an extended programme of work undertaken in connection with photographic lenses for aircraft.

In 1916 it was thought desirable (partly as a precaution against the results of possible aerial attack) that for the manufacture of this important material the nation should not be dependent on a single source of supply, and the Derby Crown Glass Works, Ltd., were encouraged to commence its manufacture, and they have already been successful in producing a number of types of optical glass of good quality. Still more recently the United States—though, to a large extent, dependent on English and French resources for optical glass for war purposes—have commenced its manufacture on their own account, and have already achieved some success in this direction.

Such are the demands of war on the optical industry that towards the end of hostilities one British firm was producing twice as much optical glass as the world's total output previous to the war. In considering, further, the position of the industry after the war, it is therefore obvious that there are resources in this country for the manufacture of all the optical glass which will be required by our opticians. Nor need there be any apprehension regarding the ranges of glass which will be available for the use of the lens designer. Without any notable exception, Messrs. Chance Brothers have been able, by their previous experience and by the work of their research laboratory, established during the war, to produce glasses which, in their optical constants, cover the full range of glasses mentioned in the Jena list for 1913.

Before the war computers designed lenses to utilise existing Jena glasses of definite optical constants. It would be undesirable and unfair to British manufacturers to reverse this process completely. Computers should be prepared to do a certain amount of recalculation, and so avoid imposing on the manufacturers the wasteful task of producing a glass to imitate exactly the hazard constants obtained in the particular foreign melting used previous to the war.

PRESENTATION TO MR. J. MACWALTER.—An interesting gathering took place on Friday last in the factory of Messrs. Elliott and Sons, Park Road, Barnet, to wish farewell and God-speed to one of the employees, Mr. James Macwalter, who had held a responsible position with the firm for thirty years. Mr. Greenwood, in handing Mr. Macwalter a handsome gold watch chain, on behalf of the employees, said they had come to look upon Mr. Macwalter as a fixture. They were sorry to lose Mr. Macwalter, and wished him every success in the future. Mr. Hubert Elliott, on behalf of the directors, then handed Mr. Macwalter a beautiful gold semi-hunter watch, and, in doing so, said how much the directors appreciated the valuable work done by Mr. Macwalter.

THE BRITISH PHOTOGRAPHIC RESEARCH ASSOCIATION.

PROGRAMME OF RESEARCH.

The following communication has been issued by the Council:—

The urgent necessity for the future development of British industry on a more scientific basis than hitherto has been recognised by the Government, who have placed a million sterling at the disposal of the Department of Scientific and Industrial Research for the purpose of encouraging research and its application to the development of British industries. The Advisory Council for Industrial and Scientific Research, after consultation with manufacturers and scientists, recommended that grants should be expended on a co-operative basis in the form of liberal contributions by the department towards the funds raised voluntarily by associations of manufacturers, established for the purpose of research. By this method the systematic development of research and its application to industry is carried out under the direct control of the industries themselves, and the co-operation of the firms in one industry will enable research work to be undertaken which could not have been dealt with by an individual firm.

The manufacturers of photographic materials and apparatus were the first to form an association to avail themselves of the scheme, and in May, 1918, the British Photographic Research Association was formally incorporated. Dr. R. E. Slade has been appointed director of research, and laboratories have been obtained for the time being at University College, London. These laboratories are under the control of the director of research and are distinct from the teaching laboratories.

The Association will carry out research in photography, photo-chemistry and other related subjects, with a view to the general increase of knowledge of these subjects, improving methods of manufacturing photographic materials and discovering new photographic processes.

It is not the intention of the Association to attempt to standardise throughout the manufacturing methods of the photographic industry. Manufacturers will always insist on determining for themselves the lines on which their business shall develop. It is the aim of the Association, by applying scientific methods, to obtain knowledge which will be of the widest application to the industry, which may be utilised by each manufacturer for the development of his own particular processes.

Pure research into the scientific basis of photography, and into related subjects, such as colloidal chemistry and photo-chemistry, will be carried out for the increase of knowledge, without necessarily any immediate application of the results to manufacturing processes. These researches should open up new and important fields of applied research, and advantage will immediately be taken of any results of research which appear likely to lead to the progress of the photographic industry.

Among pure researches which are contemplated are the following:—

- Investigations into the fundamental properties of silver halides, and of the effects of various substances on these properties.
- Investigations into the physical and chemical properties of gelatine and other similar colloids.
- Investigations of a wide range of photo-chemical reactions.
- Investigations into colloidal chemistry.
- Investigations into the theory of processes of colour photography.

Publication of the results of pure research will be made from time to time in accordance with the rules of the Association.

Applied research will be undertaken to improve products now being manufactured, to improve methods of manufacture, and to introduce new photographic processes. These researches may be undertaken with a view to improving some process which is well known to require improvement or to overcome some difficulty which has arisen in manufacture, or they may be undertaken when some advance in pure science has been made which it seems possible to apply to photography.

Among the subjects of applied research will be the following:—

- Investigation of desensitising and reducing agents on sensitive materials, with particular reference to insensitive spots in plates and papers, and impurities in the raw materials used.
- Studies of the properties of various samples of gelatine with a view to arriving at the causes of the effects they produce and ultimately to obtain a standardisation and improvement of the product.

Investigation of various subjects relating to the construction of photographic apparatus, such as matt and semi-matt enamels, methods of treating wood, canvas and leather, and the production of special alloys.

Investigation of paper and cardboard.

Colour photography.

Improvements in apparatus and material for commercial and national purposes.

Researches will be carried out in the laboratory of the Association, the Director of Research and his staff, or in other places by his special direction.

In applied research the Association desires that its work should end at the point where a theoretical laboratory result has been gained. It adopts as a guiding principle that its interest in and care for any one of its achievements should not relax until it shall have been adopted by the industry on a practical manufacturing scale; to this end the Association may make appropriate arrangements for trying on or for experimental work with private individuals or manufacturing firms with a view to testing on a practical basis its laboratory result; knowledge of processes so achieved being at the disposal of all members.

The Association desires to be of the utmost possible use to its members individually, limited only by its position as trustee for the interests of the industry as a whole. It will welcome enquiries from members on technical points and will endeavour to reply helpfully either direct or by indicating sources of information. It has begun the foundation of its working library and is preparing for the translation and digestion of relevant scientific reports from home and foreign sources to be eventually available to members as a centre of knowledge. It may also, subject always to the aforesaid limitation, carry out specific items of research for individual members. Application for such services would require the approval of the Council with whom would be made such detailed arrangements as may be deemed appropriate in each case.

The programme set forth above covers a vast field for research; but with the help of members, from whom suggestions will always be welcomed, the Association hopes to explore first the most productive portions of this field. Results have already been obtained in the laboratory, which it is expected will have a wide application to the industry.

THE PHYSICAL CHARACTERISTICS OF X-RAY FLUORESCENT INTENSIFYING SCREENS.

(Abstract of a paper from the Eastman Research Laboratory.)

The use of fluorescent screens for the intensification of exposure is of widespread practice and of considerable importance in practical X-ray photography or roentgenology. Also in the work of Hull, St. John, and others, the fluorescent screen has been employed to reduce the lengthy exposures of X-ray spectroscopic investigations that are dependent on the photographic plate for record.

In dealing with fluorescent phenomena dependent on an X-ray tube for excitation there are two types to be considered, both of which may be utilised for photographic intensification. The first type is that of true characteristic radiation, the second ultra-violet and visible fluorescent radiation. The true characteristic radiations of all the elements which are feasible to use are within that range of frequencies usually termed X-rays. Hence, the laws pertaining to high frequency radiation govern the photographic use of screens dependent on this principle. In the case of fluorescent emission of ordinary light the laws of ordinary optics apply.

Of these two types of intensifying screens, the second has proven to be far more efficient in practical usage.

Of the materials which fluoresce to X-rays in the range of frequencies from the ultra-violet to the red, there are only a few which can be used efficiently for photographic intensification. All of these substances must be in crystalline state. Of these, crystalline calcium tungstate is by far the best with present photographic X-ray materials. The salt is usually powdered and coated with a suitable binder on a support of some material of slight X-ray absorption, such as cardboard or celluloid. This screen is then placed in contact with the photographic surface and exposure made through either the screen or the photographic plate or film.

The efficiency of any radiator as a source of photographic stimu-

lation depends primarily on the comparative spectral distribution of the energy of the radiator and the spectral sensibility of the particular photographic plates used. While these relations have not been determined as yet on an equal energy basis for X-ray materials, qualitative analyses have been made.

The fluorescent spectra of calcium tungstate were obtained, using a Hilger quartz spectrograph. A Coolidge tube of medium focus was used, the length of exposures averaging 1,000 milliamperes minutes at 8-inch distance from the target to the screen.

Spectrograms were made with the tube operating at 40 K.V., 60 K.V., and 80 K.V. (R.M.S.).

It was found in general the fluorescent spectrum of calcium tungstate as used in the screens examined extended from about 3,600 to 5,200 A.U. at the voltages normally used in radiographic practice. This emission coincides remarkably well with the wave-length sensibility waves of the X-ray plates which are being mostly used.

MILLARD B. HOBSON

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Working for Amateurs.

AMATEUR photographers of Great Britain spend thousands of pounds annually in having exposures "finished." Most of this finishing is summer work, and this being the first peace summer, it is natural to suppose that more amateur photography—and therefore more finishing—than usual will be done. Now amateur finishing includes development, intensification, reduction, and re-touching of negatives; printing, enlarging, and slide making; mounting and working up; so it might be surmised that the thousands spent on it find their way to professionals.

This, however, is not quite the case, for though certain professionals undertake such work, many more leave it to the local drug store. A great deal is also done by specialist firms, but leaving this out there is always some for the local professional who cares to cater for it.

For a studio to undertake amateur work with success, method and a certain amount of special tackle are indispensable. Given these, and there is no reason why a handsome profit should not result. The necessity for system cannot be over-emphasised. It is worse than useless taking in spoils for development and handing them to the operator or bromide printer to put through with his own work. Nine times out of ten either the studio work or the spoils, or both, would suffer.

Again, when quantities come along, it is extremely easy to mix up orders—unless the possibility is obviated by rigid book-keeping—and when amateurs' negatives get mixed or go astray it is often a serious matter.

No case of reacting here. Every spool, pack, or plate taken in for development must be allotted a number which must be booked along with the customer's name, and kept strictly to that spool, pack, or plate right through. At the same time, the number must not be conspicuous. The kind of numbering done on many studio negatives would not be permissible, and so certain firms avoid marking amateur negatives at all, but keep each in a numbered wallet, and exercise great care to prevent negatives and wallets from becoming mixed. This is very difficult when developing has to be done, and a simpler system is to number each plate or film on the extreme edge, writing with an H.B. pencil very small.

The most important line is development of spoils, of which there are no less than sixteen common sizes. The best results are obtained by tank, and for large quantities of this work special tanks can be bought which take the films doubled over wires and hanging vertically, the ends being kept down by a weighted clip. The time and temperature method is advisable, normal development being given irrespective of exposure, and no after-treatment used to improve the result unless such is arranged for with the customer, who may be quite willing to pay for intensification or reduction, but may or may not desire it.

Various developers are used, but pyro-soda has by no means the

pull here that it has in studio work. Metol-hydroquinone has certain advantages, but perhaps the best of all is pyro-metol-hydroquinone, a formula for which was introduced some years ago by Messrs. Kodak, and has enjoyed much popularity since. It will be found toward the end of this article with other formulæ useful in amateur work.

Plain hypo or acid fixing may be used for films. With plain hypo it is possible to obviate the risk of metallic staining—due to corrosion of the hanging wires—by allowing the wires to silver-plate themselves, which they will do if given no cleaning beyond a rinse after each batch. Using acid fixing, there is some uncertainty, and many workers laboriously scrub the wires before and after using. The same applies to plate racks and pack film rods. The latter are metallic, and have twelve clips each, thus enabling one to develop the packs without mixing them. The use of these wires, rods, and racks makes the development and fixing of large batches a matter of minutes only.

The safest method of washing films is hand changing. The three-box washer is very serviceable for spools, as with it three batches can be washed at once. A type of this washer has been already described in the Journal, but for those not familiar with it a rough outline here will not be out of place. Briefly, the washer consists of three trays, each from four to seven inches deep, put in stair fashion, the water running into the top one and the overflow syphoning off into the second, and so on to the third, and then to the final outlet.

Films are put into the bottom dish for five minutes, after which they are moved one by one into the second, where they have another five minutes, being then moved singly into the top dish for a further ten minutes. A single tap will keep as many as sixty spools washing with a minimum of attendance. Spool film is best dried in a cabinet, hung from clips, with the bottom ends weighted. An electric fan in the top of the cabinet will greatly speed up the drying.

As already mentioned, after-treatment is best undertaken by arrangement with the customer, and here a good salesman is useful. By pointing out to clients what can and what cannot be done with a negative orders are improved and reputation and income increased. At the same time, it is wise not to accept responsibility when taking on intensification or reduction of negatives which have been developed elsewhere.

A second big item in amateur work is printing. For this work gaslight paper is essential, owing to its capacity for covering all kinds of negatives. The two varieties, soft and vigorous, are necessary, as is also a powerful light-source, which can be toned down when required, as amateur negatives vary greatly in density as well as quality. Black and white prints with narrow white edges are usual, though it pays to quote for sepia and mounted work, and also bromide, carbon, and platinum at times.

For dealing with quantities special printing cabinets are made which accommodate four printers, the lamp being a half-watt or a mercury tube placed centrally between the four desks.

Masks are supplied by the papermakers for the masking of all sizes. The best of these are the transparent ones, as they show at a glance if any part of the picture is being cut out—a point that must be carefully watched.

Enlarging for amateurs is profitable work if well done. Here again a powerful light-source is necessary, and gaslight paper also plays its part, though naturally bromide holds the palm. The usual lamp is the arc, but mercury tubes or a 2,000 half-watt will serve very well and require less attention. A hard and a soft bromide paper must be kept on hand, and for very thin flat negatives a vigorous gaslight paper will be found almost indispensable.

The method of working commonly applied to studio enlarging—making the best of each job and using discretion or artistic talent as to cutting out, vignetting, etc.—cannot be applied to amateur work without the customer's knowledge. This is another point where good salesmanship tells. Without specific instructions, it is always safe to make the picture dead sharp all over, and to include every bit of the negative, good or bad. Should one get an order in the dark-room for a 10 x 12 "all on and fill the paper" from a postcard negative—and this happens even in specialist houses—it is merely a sign of want of attention on the part of salesman or recep-

tionist, and the best that the enlarger can do is to make a picture measuring 12 x 8½ approximately.

Minor improvements, such as shading, vignetting of dirty skies, or printing-in dense detail, are, of course, advisable, but cutting off, soft focussing, etc., are best left alone unless ordered.

Working with films a difficulty may be experienced in fixing them in the carrier. For this two really good ½-plate glasses will be needed and a set of masks. These masks had better be cut specially, and the following sizes will cover most negatives, if occasionally helped out with a right-angled strip or a straight piece.

The figures indicate inside measurements only, the outer dimensions being 6½ ins. x 4¾ ins. in each case:—2½ x 1½, 2¾ x 2, 2¾ x 2¾, 3¾ x 2¾, 4¾ x 3¾, 5¾ x 5¾, 5¾ x 3¾, 5¾ x 4¾.

When correctly fitted to the negative a mask should show a 1/16-in. line all round. This line shows at once that the whole picture is in evidence, and that no small detail has been covered.

Another way of avoiding the risk of "cutting off" is to do without masks and work on to a black easel (to prevent fog), but the more usual practice is the use of masks.

Adjusting the films in the carrier can be facilitated by working on a window—illuminated from beneath—let into the bench. This dodge will save its cost in a busy shop within a week.

To cater properly for amateur enlarging good apparatus is a *sine qua non*. The demands range from ½-plate to 30 x 40 and larger, and there is no limit to possible requirements in quality. At the same time, adequate prices can be obtained for this work.

Copying and slide making are in demand by amateurs. To cater for either of these lines the photographer must be able to cope with a variety of originals. A good copying bench capable of a big range, a selection of fast, slow, and process plates, and there should be no difficulty in obliging and profiting by the most fastidious or exacting client.

The following tip, however, may be useful. When dealing with an original that is not critically sharp, include on the plate, if possible, a small piece of letterpress. This forestalls any complaint of want of definition in the new negative.

The making of slides will necessitate the use of at least two varieties of plate—bromide and gaslight. Process slides may also come in handy, but on no account should one plate be made to cover everything. The use of the most suitable kind, and also recourse to the enlarger occasionally, will pay in the end.

Mounting, spotting, and working up and retouching are all profitable lines with amateur work. The former should, of course, be plain—i.e., the professional's name must not appear on any mount—beyond that it is usually safe to work by one's own judgment. Spotting, etc., can be measured by price or otherwise.

It will be gathered from the preceding that to cope with any quantity of amateur work some amount of apparatus and formulæ more than what is usual in studio work will be necessary. Developing tanks, drying cabinets, and drums, and printing machines are the most important pieces of apparatus, and they are supplied by the manufacturing firms who make a specialty of amateur requirements.

The practical man can make the cabinets for himself; the tanks and printing-room appliances are better bought. A film drying cabinet can be made from a large cupboard by adding cross-bars to the top and removing part of the floor to allow ventilation. For quick drying a hole can be cut in the roof and an electric fan placed above to blow downwards. On the cross-bars, not less than 4 ins. apart, clips are fixed to hold the films, the bottom ends of which are held down by other and heavier clips. Letter clips will serve, or the special clips made by photographic manufacturers for the job.

With regard to formulæ, the use of those recommended by the particular maker is advisable. The following, however, are very serviceable:—

For tank development of films:—

Metol	130 grs.
Hydroquinone	1 oz. 50 grs.
Soda sulphite	1½ lb.
Soda carbonate	1½ lb.
Pyro	200 grs.
Potassium bromide	60 grs.

This formula was introduced by Messrs. Kodak, the quantities

given being those sufficient for one of the Kodak tanks. It is an exceptionally good developer, with great keeping properties.

For prints:—

Amidol	200 grs.
Soda sulphite	5 oz.
Potassium bromide	30 grs.
Water	60 oz.

Suitable for all makes of gaslight paper and for bromides if diluted with one part of water to every two parts of developer. This formula has the advantage of giving excellent results with different makes and varieties of paper. Where metol-hydroquinone is preferred, the proportions advised by the papermaker should be adhered to. The advantage of M. Q. is its keeping quality, which allows the making up of stock solutions.

For intensifying plate negatives:—

Soda sulphite	4 oz.
Iodide of mercury	90 grs.
Water	10 ozs.

The intensifier, if kept in the dark, will last fairly well, and is safer with strange negatives than mercury-ammonia.

For films, copper ferricyanide is better than a mercuric solution. This tones them red, and greatly increases the scale of contrast. Another method of intensifying films is to sulphide-tone them.

Having run over the gamut of amateur work, a word as to prices will not be out of place. To give a detailed list of prices for the hundred and one large and small orders usual with amateurs would involve too much space. Such a list, however, might be obtained from a manufacturer, though the practical business man need not hesitate to draw up his own charges.

Prices should be kept as high as the class of customer and the operation will allow, but small orders offering perhaps but a shilling or two should not be neglected. The making of a single postcard enlargement for an enthusiast may prove a big advertisement and lead to further and better orders. On the whole, amateur photographers are an appreciative class, and don't mind paying for good stuff.—**THEWIT.**

Renovating Picture Frames, &c.

A most useful varnish to use for stained wood or composition frames, which makes the appearance equal to new, can be made of best "pale goldsize." If we wish to use it on an old composition frame, the frame should be washed over first with soap and water, and put aside until perfectly dry. Then the parts which are rubbed or knocked should be touched up with stain to match; then, using the "goldsize" as ordinary varnish, put on with a soft brush and put the frame aside in a place to dry, free from dust. It dries quickly, and if done nicely makes the frame as good as new. In the case of ordinary oak frames, which have to be stained or darkened, these can be coated over with the "goldsize," and if it gives too much gloss the "goldsize" can be thinned down with spirits of turpentine until it gives just the required finish. If the "goldsize" is of good quality it should dry as hard as a stone. If it does not dry perfectly, add a little turpentine to the "goldsize" previous to using.—**E. HINGO.**

New Materials, &c.

AKRON DRY MOUNTING TISSUE.—The Akron Manufacturing Co., 369, High Road, Tottenham, London, N.17, send us samples of a dry-mounting tissue which they are newly introducing upon the market. The tissue is evidently of an exceedingly good quality, highly flexible and free from colour, whilst no fault can be found with it in the readiness with which it is handled in the press. It is supplied in rolls of 30 feet by 25 inches, price 7s. 6d., or 30 feet by 31 inches, price 9s. 6d. In cut pieces it is supplied in gross packets ranging from 3½ by 2½ to 20 by 16. In half-plate size the price is 4s. 4d. per gross; whole-plate 8s. It is also supplied in quires of 20 by 24 inches, price 10s.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

TUESDAY, APRIL 15.

Royal Photographic Society. "Colour Values in Monochrome and a Viewing Filter as an Aid to Obtaining Them." F. F. Renwick, F.I.C.
Hackney Photographic Society. "Opening of One-Man Display." H. E. Wood.
Manchester Amateur Photographic Society. Demonstration: "Copying." T. E. Simpson.

WEDNESDAY, APRIL 16.

Croydon Camera Club.—"A Walk in Wanstead Park." A. E. FARRERS.
Leith Amateur Photographic Association.—Social Meeting, with Whist.
Dennistoun Amateur Photographic Association.—Annual Exhibition.

THURSDAY, APRIL 17.

Huddersfield Naturalist and Photographic Society.—Lantern Lecture. A. G. Ellis.
Hammersmith (Hampshire House) Photographic Society.—Annual Exhibition.
Ridley and District Photographic Society.—Monthly Competition. "Winter Landscape."
Tonbridge Wells Amateur Photographic Association.—Demonstration: "Auto-Tank Development." R. J. Sells.

ROYAL PHOTOGRAPHIC SOCIETY.

The meeting of Tuesday evening last was one of members only, held for the purpose of discussing the formation of a scientific group within the Society. The discussion was one to which reference is advisedly postponed until the official report of the proceedings in the Society's Journal.

CROYDON CAMERA CLUB.

DR F. KNOTT, an old member of the club, though far from a veteran in years, gave a lecture, entitled "Visual Psychology," which escaped improvement by the secretary, probably owing to doubt as to its significance. Others shared this, for some came prepared to hear a dissertation on the mystic and occult; some conjectured a certain lovely maiden beloved by Cupid might receive attention; whilst the majority preferred to "wait and see," and, when last week they saw, found seeing was not necessarily believing. As a matter of fact, Mr Foster Brigham was down for the date, but remained up at Scarborough. However, he sent such a nice letter of apology, with references to "unforeseen circumstance" and the "diffidil disease," that all forgive his absence.

Dr. Knott's paper consisted of two parts—the psychology of form and that of colour. It took over an hour to deliver, read at express speed, but with excellent articulation. The subject was treated in a truly scientific manner, yet in a way readily to be understood by an unpsychological audience. The few extracts selected for report give no idea of its scope.

Psychology, he said, is a large subject, and the visual branch by no means its smallest. It consists of the scientific study of the nature and course of experience. We know a thing, and sometimes we know that we know a thing, but more rarely do we know that we know that we know a thing (*sic*, nothing could be plainer). Classification is important. There are many kinds of sensations, and we are equipped with receptors for all the chief kinds of physical energy, except electricity. Light is especially interesting to photographers as predominantly visual creatures. The eye may be considered as a little camera, with its lens, more or less perfect, capable of being focused and stopped down, with the retina acting as a focusing screen, the image being upside down, which is reversed by the brain.

The chief faults of the eye correspond with those from which lenses suffer, spherical aberration and astigmatism being present, amongst others. Optical lenses are made of transparent glass, but the media of the human eye are slightly turbid, causing "irradiation," which has the same subjective effect on objects as actual turbidity has on objective things. The angle of view of the two eyes is enormous, no less than 180 deg. in the horizontal meridian and 120 deg. in the vertical, the images received being minutely finished in the centre, and only roughly sketched at the borders.

There is one spot of extreme sensitiveness in the retina, and another of absolute blindness at the attachment of the optic nerve; but, as in binocular vision the two blind spots never coincide, the

defect is unnoticed; also, they almost invariably affect those parts of the field to which, at the moment, attention is not directed. The blind spot is so large that it might prevent our seeing eleven full moons placed in a row. (It transpired in the discussion that this phenomenon has no connection with the two moons seen side by side under certain conditions.)

All are colour blind, the outermost retinal zone being absolutely blind to colour; then come intermediate zones with partial colour vision, and, finally, the innermost with complete colour perception. The lecturer then passed on to an exhaustive consideration of binocular vision, perspective, and the theory of colour and its relation to vision. He also showed a large number of highly interesting optical illusions dealing with form, magnitudes, and colour. Considerations of time and space preclude these being touched upon. It should, however, be mentioned that Mr. Sellors alleged that he saw quite correctly many things which correctly he should have seen incorrectly—typical of the secretary's perversity.

In the discussion a point raised by Mr. Reynolds resulted in a pretty flare-up between him and Mr. Purkis, the "office boy" energetically fanning the flames, only to find himself enveloped. If any reader with a kind heart and sufficient knowledge can throw any light on the points in dispute, it may avert a repetition of the peculiar triangular duel described by Marryat. The facts are as follows: A cardboard disc, painted blue and yellow, on being revolved, appeared white. An assumption was then made that the same colours be applied in minute dots in juxtaposition on a piece of white cardboard, when it was agreed that, viewed from a distance, a green sensation would be received. Therefore, why a white sensation in the first place and a green one in the second? About an hour after a hearty vote of thanks had been accorded the doctor for an evening of unusual interest the disputants separated. Mr. Purkis departed resolved to think the matter out; the office boy left with an equally firm resolve in an opposite direction, and Mr. Reynolds and his gentle, compassionate smile melted into the night—a smile, by the way, which simply touts for trouble.

SHEFFIELD AND DISTRICT PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.—The usual monthly meeting of the above Association was held in Stephenson's Café, Sheffield, on April 2. There was a good attendance of members, and one new member was enrolled. The evening was occupied in a general discussion on the following subjects: Minimum prices for postcards, the assistant question, keeping a register of employees open to engagement, the training of disabled men as assistants, etc. The secretary was instructed to ascertain full particulars of the Government's proposition for the training of demobilised men with a view to commencing in business as photographers. It was decided to make an effort to induce district photographers to become members of the Association. A very pleasant evening was spent, and members seemed to take more interest in the future of the Association than has been apparent for some time. The subject for discussion at the next meeting is, "The Best Artificial Lighting for Studio Portraiture." The Association is open for new members. The hon. secretary's address is 137, Pinstone Street, Sheffield. Manufacturers are invited to demonstrate new goods, apparatus, or novelties at any of the Association's meetings.

Commercial & Legal Intelligence.

A PHOTOGRAPHER'S AFFAIRS.—At the London Bankruptcy Court, on Friday last, before Mr. Registrar Franke, the public examination was appointed to be held of Harold Aylmer Jones, photographer, 7, Gloucester Terrace, Kensington, W., formerly of 30, Hill Street, Richmond, who alleged his failure to have been caused through loss on the business at 7, Gloucester Terrace and loss of business through domestic differences with his wife, who had obtained judgment against him for arrears of an allowance under an Order of the Court. Upon the case being called on for hearing, Mr. F. T. Garton, who acted as Official Receiver, said the debtor had given the Court a good deal of trouble. He had written to say that he had filed the best statement of affairs it was possible for him to make out, and

he asked for an adjournment on the ground of ill-health, but he had not fortified his application with a medical certificate.

The statement of affairs was very incomplete, and the debtor had only attended once upon the bankruptcy officials since he was previously before the Court; therefore, he asked that the examination might be adjourned *sine die*. When the debtor appeared at the Court on the last occasion he certainly looked unwell, but as he was not present on this occasion he thought the examination could be adjourned *sine die*.

The Registrar granted the application upon the ground that the debtor had not given a reasonable excuse for his absence.

News and Notes.

BROMOIL PORTRAITS.—While the exhibitions testify to the beautiful quality attainable in portraits made in Bromoil, professional photographers, with one or two exceptions, have ignored the process altogether. The technical experience necessary is obviously one reason for this, and therefore we may refer to the work in this field done by Mr. F. T. Usher, of Durham House, Cumberland Road, St. Albans, who is a maker of bromoil prints and enlargements from photographers' negatives. We recently had an opportunity of seeing the fine quality which characterises Mr. Usher's bromoils, and has its origin in the fact that the work is done out of a strong liking for the technique of the process and a desire to realise its possibilities in yielding results of artistic excellence. By customers able to appreciate the distinctive merits of the oil-pigment prints a high price is willingly paid, and therefore photographers who are in the position of being asked for such work will be glad to make a note of the source from which it may be obtained.

SILVERLINE SKETCH PORTRAITS.—In referring the other week to the special service for photographers now being offered by Mr. D. Charles, 363, Garratt Lane, Earlsfield, S.W.18, we mentioned a specialty to which we may now refer as the result of examining a considerable number of examples of his work in this branch which Mr. Charles has sent us. These are "silverline" portraits in the sketch style, and with the necessary freehand work introduced photographically from a pencil drawing. The reproduction of the pencil effect is very well done and the vignetting of the subject itself equally good. We have our own opinion as to the artistic merit of ringling a photographic image with pencil work, but the demand for such sketch embellishments of vignetted portraits is widespread, and therefore photographers anxious to show their customers something distinctive will be glad to avail themselves of Mr. Charles's services. He is a specialist in blocking-out and vignetting work and the prints before us show the very successful application of these methods to exceedingly diverse subjects.

WHITE-MARGIN MASKS.—The firm of Artista, 5, Rue de Montfaucon, Paris, 11e., send us samples of the white-margin masks which they supply in a wide range of sizes for the making of prints in which an even white margin is desired. They are of two patterns, for plates and films respectively. The former consists of a strongly made cardboard frame having an aperture the size of the negative. Around the aperture is attached a mask of non-actinic paper which, when the negative is printed gives the required white margin. In the case of the masks for film negatives a hinged cardboard back is provided in order to facilitate the introduction of the film negative and the paper behind the mask. Those who have had much occasion to handle film negatives in making prints of this kind will appreciate this little device, which immensely simplifies the adjustment of the negative and paper. The whole mask, is of course, intended to be placed in the printing frame or it may be used, as can that for glass negatives, on the bed of a box printer. The masks can also be obtained with oval apertures as well as with those of fancy outline. A good feature common to all of them is that they are made so as to utilise the maximum area of the negative. The sizes range from vest pocket to half-plate and the prices from 3d. to 7d. in the case of masks for glass negatives and from 6d. to 1s. 3d. in the case of those for film. Other and larger sizes can be made on application.

Correspondence.

- Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- We do not undertake responsibility for the opinions expressed by our correspondents.

COMBINED DEVELOPER AND FIXER FOR FERROTYPE PLATES.

To the Editors.

Gentlemen,—I see in your "Answers to Correspondents" to-day that you are unable to furnish a querist with development formula for photo buttons. In pre-war times I frequently made up the following for street operators: The plates are developed (and partly fixed at the same time) for two to three minutes, according to the temperature, and are then examined in daylight and fixed in plain hypo. More ammonia added to the developer gives more vigour, if required.

Water, to make	40 ozs. fluid
Hydroquinone ..	½ oz.
Soda sulphite	4 ozs.
Soda carbonate	4 ozs.
Hypo.	8 ozs.
Liq. ammonia. 880	2 fl. ozs.

E. W.

A PLATE-CHANGING CASE.

To the Editors.

Gentlemen,—I have found the use of a changing-box a necessity on several occasions, and perhaps the following description and illustration of one I constructed for my own use may be of service to some other of your readers. I bought a gramophone-record case for four shillings, which took my half-plate camera, three double dark-slides, box of plates, empty plate-box, and focussing cloth, all nicely packed. From the construction of the case it struck me there was a possibility of using it also for plate changing. The lid of the box is hinged, and as it drops forward forms the bottom

of the changing-bag. A double thickness of turkey red twill is used for the top and sides, and for the purpose of keeping the material in position on the box a band of strong wide elastic is employed. A small piece of leather covers the space between the lid and the box—i.e., the portion where it is hinged, so as to ensure it being perfectly light-tight. The sides of the fabric are sewn to the lid of the box, and when not in use this fabric folds up and fits inside the lid and takes up but very little space. A small buckle and strap completes the outfit, which I consider the cheapest and most compact I have yet seen, and one which has stood severe testing against fog.—Yours truly,

Barrow-in-Furness

A. DREWITT

FORTHCOMING EXHIBITIONS.

April 17 to May 22.—Hammersmith Hampshire House Photographic Society Annual Exhibition. Two open classes. Joint secretaries, J. O. Abraham, 41, Hamilton Terrace, London, N.W.8; A. H. Page, 12, Lime Grove, London, W.12

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

E. W. AND A. D.—We are much obliged to you for your communication, which you will see we are using.

G. A.—None, except that if you do not trade in your own name it is necessary to register the business. Particulars of registration you can get from the Registrar of Business Names, 59, Russell Square, London, W.C. 1

A. H.—You can obtain hydrofluoric acid from Messrs. Johnsons, Ltd., 23, Cross Street, Finsbury, E.C. The price of the commercial acid is about 1s. per pound, 2s. or 3s. per pound for purer varieties. The acid has to be sent in a gutta percha bottle.

A. A.—You should do very well with the two windows for all but standing figures: for these we should advise, say, three 1,000 c.p. half watts to give a top light. If the lamps are made adjustable in height you could also use them for evening work.

G. H.—We believe the best terms of insurance are obtainable by members of the Professional Photographers' Association, by arrangement made with the latter, by the Eagle, Star, and British Dominions Company, although we have no information as to the precise rate. You should apply to the Secretary, Professional Photographers' Association, 80, Albany Street, London, N.W.

H. W. H.—The book you want is the "Portrait Studio," issued by our publishers, price 10d., post free. We presume you mean cabinet full-length and busts, in which case the longest focus you can use for full lengths is 8½ ins., or 10½ ins. for busts. These foci are given on the assumption that you have altogether 18 ft. of room, say, 3 ft. for the sitter and background and 3 ft. for the camera and operator.

E. V.—All the plate and paper manufacturers are regular buyers of attractive child studies for specimen cards. Apart from them, other buyers are the postcard publishers, such as the Rotary Photographic Company, West Drayton, Middlesex; Philip G. Hunt and Co., 332, Balfour High Road, London, S.W. 17; and Lilywhite, Ltd., Dunkirk Mills, Halifax. These firms usually only buy in lots of six.

A. E.—For such subjects as furniture the lighting must be more even, and the lamps may be more directly over the articles than for portraiture. Still, 5 ft. seems to be too near the background. As length of exposure is of no account, only as many lamps as are required need be lighted; there should be a separate switch for each. If there is a white ceiling above the reflected light, it will help greatly in softening the shadows.

G. I.—The angle metal slides were previously almost exclusively a German specialty. We do not know what firms here have been making slides during the war, but we should imagine that the Houghton-Butcher Manufacturing Company, Clifford Road, Walthamstow, London, E.17, is the only one which is likely to have taken up the matter. You might, however, also try a firm in your town, Messrs. Haseler and Sons, 94, Bridge Street, West.

G. F.—We should certainly advise you to put the glass roof and side windows at the south end of your proposed studio, that is to have the background at the house end. You will thus not only avoid the sun, but get better lighting. Also, if possible, make the

- roof 10 ft. long. the same as the side light. This need not go right across the roof, 7 ft. will be enough. This will save blinds and the cost of glass. In the side light there is no need to have glass lower than 3 ft. from the floor.
- A. H.—We do not think for a minute it would pay you to tinker with the bromide paper in the way of "renovating" it with such solutions as weak bichromate or permanganate. Although it is possible to make the paper clean working by such means, it slows down the emulsion to something like the speed of a gaslight paper. Probably the best thing you can do with it is to burn it and send the ashes to a firm of refiners, such as Messrs. Johnson and Sons, 23, Cross Street, Finsbury, London, E.C.
- B. G.—1. The 3C. lens will not be so satisfactory for groups when used at $f/8$ as an ordinary $f/8$ R.R. 2. Very doubtful. There is so little depth with an $f/2.2$ lens that enlargements will suffer from this cause. We think that you are exceeding the useful maximum of aperture in choosing one so large as $f/2.2$. We should say that the very largest aperture which is really useful is $f/3$ and, better, $f/4$. 3. We do not know anything of the chromatic correction of the C3, but as these lenses cover a comparatively narrow angle we should imagine that the corrections over that angle are of a high order.
- J. W.—We are unable to diagnose with any certainty the cause of the markings on the postcard negatives. The best suggestion that we can make is that one marking appears to be due to some slight reflection in the camera, say, from some minute polished metal surface in the near neighbourhood of the plate. The light band across the negative of the three ships might, perhaps, be due to some desensitising action from a hinge of a dark-slide, but this is only conjecture. An expert retoucher could very easily take out what appears to be the drying mark in the seascape negative, or the plate might be coated on the back with ground-glass varnish or "Bildup" and worked up with a pencil or crayon.
- J. B.—Certainly some people do not suffer at all from developer poisoning. There is no difference, for practical purposes, between M.Q. and amidol as regards production of stress marks. There is, perhaps, a slight advantage in using amidol for prints to be toned by hypo-alum or sulphide in comparison with M.Q., but the difference is very slight. We do not know that iodide improves the tone when added to the bleaching bath. Discoloration of the whites is usually caused by over-exposure and insufficient development of the black prints, but there is always a certain amount of degradation. You should use isochromatic plates, say, of about 100 to 150 H. and D., with a K2 filter. We should prefer pyro-soda to pyro-metol.
- E. W.—The ordinary half-watt lamps are not suitable on account of the size of the filament area. No doubt very shortly the focus type of lamp will be again available from the General Electric Company, 67, Queen Victoria Street, London, E.C. But we should think you would have no difficulty in using the enclosed arc lamp made by the Westminster Engineering Co., Victoria Road, Willesden Junction, N.W. We have not heard that there has been any difficulty in getting carbons for these lamps, and the power of a small lamp costing about 50s. is sufficient for all ordinary enlarging. The chemical focus difficulty does arise with some few lenses of the modern type, but the R. R. is almost invariably free from it.
- H. P.—1. We should say that the light of the lamp has not been sufficiently diffused with a white reflector. The means of illumination described by "Practicus" is quite sufficient for negatives of much larger size than yours. You may, perhaps, be sufficiently interested to refer to the "B.J." of March 30, 1917, on page 160 of which is described a similar enlarging arrangement used by Mr. Marshall, of Henley-on-Thames. The drawings in this issue will give you some idea as to arranging the lamp and reflecting screen. Certainly you can use a condenser-enlarger, of which we believe Billcliff's is a very suitable one for the purpose. 2. For making negatives $1\frac{1}{2}$ by 2 ins. a 5-in. Cooke $f/3.5$ would be excellent, although many cheap studios use a 7-in. or 8-in. lens, if space permits, on account of the better "drawing," but depth of focus is then very much less.
- J. C.—We should think that in your circumstances your best plan would be to use either one of the high-power focus half-watt lamps in conjunction with a condenser or a battery of filament

lamps, half-watt or otherwise, in a reflecting-box, so as to provide intense diffused illumination of the negative after the manner of the enlarging cabinet sold by Messrs. Marion. Either of these plans would be convenient and satisfactory with alternating current, whereas even with a good arc-lamp alternating current is the cause of a good deal of trouble. Judging from your sketch the diffused light arrangement would probably be the better since no attention would be wanted in the way of adjusting the illumination on the easel once the lamps have been switched on, whilst with a focus lamp and a condenser there would be the constant need to alter the position of the lamp for different scales of enlargement.

HALF-WATT LAMPS.—Will you kindly advise me with regard to the lighting (electric) of new studio? The place is very low, only 8 ft. to ceiling. If I get three 1,500-watt lamps and use reflected light only, shall I be able to obtain good results, or would you advise direct diffused light? I realise the difficulty will be with standing figures. I can, perhaps, let the top part of lamps up into the ceiling about 10 ins. The size of room is 32 ft. by 14 ft., and is in all other respects most convenient and desirable. Do you consider the lowness of ceiling a serious difficulty?—R. S.

If reflected light only is used the lighting will be rather flat, but it will answer to give top light for standing figures. We should fix one lamp in this way so as to give a light to fall at about 45 deg. on the head; one a little lower, say 2 ft. to one side; and one lower still, a couple of feet nearer the background, to give a side light. All the lamps should have calico diffusers. You must consider this as a suggestion only, as the position is rather difficult.

T. G.—Depending on particular circumstances, we should say that the balance of advantage is with tank development, on account of the saving of labour and the uniformity of results. You would have no difficulty in accommodating yourself to it, the chief items being proper regard to the temperature of the contents of the tank. The developer should be moved in relation to the plates three or four times during, say, twenty minutes' development, either by lifting the rack of plates up and down, or, in the case of a water-tight tank, turning the tank up on the other end. We should say the cost of chemicals is about the same, perhaps a very little more. Teak tanks are excellent if care is used to prevent them being exposed to conditions in which they will warp, say, by putting them damp out in hot sun. One of the best we have seen is that just introduced by Messrs. Brodrick and advertised in last week's "B.J." The tank is fired enamel, and the rack is of teak. As regards the iodide, we have never heard that there is any advantage in adding it to the sulphide bath—in fact, this addition is quite new to us.

IMPORTANT NOTICE TO READERS.—Until further notice agents will supply the "B. J." to order only, as the high price prevailing for everything in connection with newspaper production prohibit the distribution of surplus copies for chance sales. It is therefore necessary in order to ensure the regular delivery of the "B. J." each week to place an order definitely with a dealer, newsagent or bookstall clerk, or to send a subscription to the publishers.

Photographs of Motor-cars. Possibly no industry uses photographic illustrations for advertising purposes as does that of the motor, and with the exception of the aeroplane none offers a better future for the commercial photographer: as with other branches of commercial work, a certain knowledge of the technique of the particular industry is a great advantage to the photographers, who should be able to appreciate ideals of construction and design and to put these points forcibly in the treatment of the photographs. A set of photographs taken to illustrate the desirable qualities of a car requires to show the arrangement of its seating, *i.e.*, its comfort for the passengers, the graceful and artistic lines of its design, and also the car speeding along a stretch of country road. Such a picture as this last, with its story of the delights of speed, goes far to making the purchasing public know and appreciate that particular model. There are still other ways in which the manufacturers might learn to rely upon the commercial photographers instead of on the draughtsmen. Details of engines, gears, universal joints, friction drives, the build of the chassis, and all the other miscellanea of the motor-car are quite easy to photograph, provided the photographer and maker work hand in hand. But such work cannot often be done in a studio, though even then nothing ought to prevent the production of satisfactory pictures. In our opinion many commercial operators rely too much on "blocking out," when a few sheets of white paper or other light material will often suffice to isolate elements of the picture from their unwanted surroundings. Many details of a car are readily amenable to this treatment, which, in any event, simplifies the work of blocking-out in cases where it is necessary.

* * *

A Card Index. Slack times occur in nearly every business, and they cannot be filled up in a better way than by making an effort to secure additional trade. It is, however, somewhat difficult to do this without some jumping-off point, which will prevent one from saying, "I want to do something, but how on earth can I do it." There can be no doubt that in photography there is no better way of advertising than through the post, and that by letter rather than by circular. The important point in starting on this work is to have a list of people to whom a direct appeal can be made with some prospect of success, though too much must not be hoped for at the beginning. It is a good plan to keep a special card index of possible customers for the sole purpose of advertising, apart from any order which may have been given previously. It need not be a large one, for the names should be carefully selected and annotated with any information which may be useful. It should contain, first, the names of customers who have given orders during any period which may have been decided upon, and the names of prominent residents whose patronage would be desirable. In every case where there is any possible excuse for making a personal reference an original letter should be written, embodying a specific suggestion, such, for example, that especially advantageous arrangements have been made for the production of coloured miniatures, or that a new style of printing, mounting, or enlarging has just been introduced, and that prints from the existing negatives can be supplied in these styles. Sometimes it will be worth enclosing a small print to indicate the class of work which is being offered. In the case of those not already customers a general letter inviting inspection of a collection of new styles may be sent. Above all, the appearance of a circular must be avoided, even to the exclusion of carbon copies. It is now possible to obtain copies made showing the texture of the typewriter ribbon, and these should each be

signed in ink in the way usual with other business letters. The notes on the cards should indicate the class of work to be offered, say, to elderly people or their families, an announcement of readiness to take portraits at the sitter's own home; to parents of babies, particulars of miniatures and enlargements; to bridal sitters, anything relating to new styles, with a reference to the possibilities of utilising portions of groups, etc., already taken. It does not matter whether any order results in the particular line suggested, the object being to find an excuse for bringing the photographer's name before customers from time to time, not as an ordinary advertisement, but as a personal matter.

THE FIXATION OF BROMIDE PRINTS.

THE article by Mr. G. F. Stine, which we reprint from an American contemporary, raises certain points in connection with the fixation of development prints on which we think it is necessary to make some comment. For while the author very properly dwells upon the importance of complete fixing and thorough washing there are certain of his recommendations which in our view are not in correspondence with the most advisable practice. To begin with—and it is a point which lies at the root of the proper handling of development prints—we do not agree that the greater number of cases of discoloration and fading in prints are due to imperfect washing. On the other hand, and it is here that we disagree with Mr. Stine, we think that both experience and theoretical considerations prove that the fault lies in want of thorough fixation. It is common knowledge that a print which has been thoroughly fixed can be given the scantiest washing without afterwards suffering any ill effects, whereas no amount of washing will remedy the state of things which is the result of incomplete fixation. In our view, too great insistence cannot be laid on the relative importance of the two operations. If fixation is thorough—and thorough fixation is not such a simple process as many photographers think it is—then the subsequent process of washing contains very little danger for the permanence of the print, even should it be improperly carried out.

Then, again, we are not altogether in agreement with Mr. Stine in the preference which he expresses for the acid hardening-fixing bath in comparison with one of plain hypo. There is no doubt whatever that a solution containing nothing but hypo dissolved in it is the best fixing bath for prints, and should be used whenever the working conditions allow of it. There may be good commercial reasons for using a bath containing other chemicals, but, speaking broadly, the average permanence of prints turned out from a studio will be greater in proportion as a plain hypo bath is used for fixing, with the important proviso that no other bath is employed which can affect the chemical composition of the hypo solution. And this is a point which brings us directly in touch with the difficulties which apparently present themselves to many photographers in their choice of the best working practice which they should adopt. Obviously a system which is sufficient for the amateur who is making only a dozen or two prints, and those of small size, at a time will not answer the purpose of the photographer who is handling hundreds, and who very frequently is working on such larger scale of numbers with prints of much greater size. Thus it is usually necessary that the person who is developing the prints should have nothing to do with fixing them, or at any rate should postpone handling them in the fixing bath until the whole batch has been developed. If an assistant is available to deal with the prints in the fixer as fast as they are developed the problem is simplified; but many photographers are under the

necessity of working single-handed, and therefore require to make their practice that which will have the least drawback as regards regularity of the prints and their permanence. The plans which thus present themselves are: (1) Passing prints straight into the hypo bath; (2) passing into a water bath, with or without running water; and (3) passing prints into a so-called stop bath. We can dismiss the first plan as impracticable except in the case of quite small prints which can be immersed in the fixer and subsequently moved about by means of a print paddle. The second plan, arresting development in a water bath, requires that a large bulk of water should be used or that there should be a brisk stream of water passing through the tank, otherwise development will go on and the prints will be irregular in depth. The third plan is to use a stop bath of weak acid or some such acid salt as potassium metabisulphite or sodium bisulphite. Any weak acid bath will arrest development immediately, and will go on doing it until the alkali transferred from the developer has neutralised the acid.

Now, these three systems impose different demands as to the composition of the fixing bath. If one transfers prints directly, without washing or stop bath, to a plain hypo solution the latter becomes discoloured from oxidised developer very much more quickly than an acid hardening-fixing bath. Although this may seem to represent a waste of hypo we are not so sure but that it has a good deal to recommend it, for the progressive discoloration of the bath is a species of danger signal, showing that a considerable number of prints have passed through it. The user will be led to discard it as soon as he judges that there is a danger of staining of the prints, and in doing that he is at the same time removing the possibility of employing a bath which has become too exhausted for satisfactory fixation. The plan may be, and very likely is, wasteful of hypo, for it may be assumed that the discoloration moves ahead of the using-up of the hypo.

To come now to the plan of washing prints between development and fixing, discoloration of a plain hypo bath is then very largely avoided, and caution requires to be used in the direction of not keeping the fixer in use until the hypo has been used up beyond the point of effectiveness. We refer to this matter in a later paragraph. It is, of course, immaterial when prints are washed in water, whether the fixer be one of plain hypo or of the acid hardening-fixing type. On the other hand, in the case of using an acid short-stop for arresting the progress of development the nature of the weak acid bath makes a very great difference. In the old days when an acid bath (of acetic acid) had to be used with the iron developer it was necessary, and the invariable practice, to wash prints in several changes of water before fixing them. If this is not done the acid and hypo form a mixture which soon contains compounds which will give rise to brownish after-stains on the prints. These ill-effects

will, of course, follow the use of such acid bath under these conditions when a modern developer is used unless the prints are washed after the acid bath. To avoid them the acid bath must be one of a kind which does not exert this decomposing action on hypo, or else substances must be added to the hypo bath itself to counteract the acid brought into it by the prints. Of these two alternatives the former is certainly the better, and consists in the use of a stop bath of what is actually free sulphurous acid, conveniently used in the form of soda bisulphite or metabisulphite. If, on the other hand, a stronger acid such as acetic or citric be used, then the hypo bath should on no account be one of plain hypo, but should contain also a fair proportion of sulphite (which will render the entering acid innocuous) or may be one of the acid hardening-fixing type which likewise contains sulphite for this purpose.

Another matter in which our own inclinations depart from those of Mr. Stine is the method suggested by him for gauging when hypo solution has been used for as much paper as it should be used for. Mr. Stine recommends the plan of passing through prints in such number that approximately 5,300 square inches of paper is supplied with 16 ounces of hypo, made up according to a particular acid hardening-fixing formula. Our objection to this suggestion is, first, that papers vary in the quantity of silver bromide contained per unit area; and, second, that such a plan disregards any loss of fixing power which the bath may sustain as a result of low temperature. In many places the fixer is by no means at the temperature of, say, 65 degrees which it should have, and any calculations based on what it should do at a normal temperature would be falsified in practice. As we have many times suggested, we think that the best test of the progress of a bath in use for fixing is to immerse in it a slip of undeveloped dry-plate and to note the time which is taken for the emulsion film to become clear. If this is more than five minutes the bath may be put aside as sufficiently exhausted for the purpose of fixing prints to be discarded. It need not, however, be wasted, since it can still be used for fixing negatives where the progress of the process can be seen. Further, we should not finish these notes without insisting, as we have done many times before, on the advantage of passing prints through two fixing baths in succession. Whether the bath is of the plain or hardening-fixing type there is a very much greater assurance of permanence if this plan be followed. Bath No. 1 should be kept in use until its removal is indicated by the test mentioned above; No. 2, which obviously has been very little taxed, should then take its place until it (No. 2) reaches the same stage, a new lot of bath being supplied for the fresh No. 2. Such a method as this is applicable upon both the largest as well as the smallest scale, and it is one which if religiously carried out will remove the complaints of stains or markings which arise from imperfect fixation.

THE GERMAN CAMERAS.—In the House of Commons, last week, Lieut.-Colonel Moore-Brabazon (Co. U., Chatham) asked the Secretary for War whether he was aware of the purchase of optical and photographic goods in Germany, and the importing of them as personal luggage into this country for re-sale by many officers, and, as trading with the enemy was still illegal, whether he would issue further orders to troops on this matter or have their baggage searched, in view of the fact that the legitimate trader was seriously handicapped by the growth of this practice?

Mr. Churchill replied that he is not aware of this, but if details of the specific cases were supplied to him, with evidence that the practice is widespread, he would consider the desirability of instituting inquiries into the matter.

THE ZEISS FACTORY.—We learn that the optical factory erected by Messrs. Zeiss on the summit of Pittacy Hill, Mill Hill, in 1910, has been acquired by a group of British spectacle-making firms, of whom Messrs. George Culver is one. The company now being formed to manufacture these goods upon a large scale looks forward to employing hundreds of workpeople in the factory and to re-erasing the large proportion of spectacle lenses imported into this country from Germany before the war. The factory, which is one of four floors, measuring 150 ft. by 40 ft., has been purchased from Messrs. Ross, who acquired it together with the other premises and assets of the Zeiss firm some two years ago. During the later stages of the war it had been used by them for the manufacture of prismatic field glasses.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
The Camera and the Lens (Jan. 10).
Managing the Sitter (Jan. 17).
Backgrounds (Jan. 24).
Studio Exposures (Jan. 31).
Artificial Lighting (Feb. 7).
Printing Processes for Portraiture (Feb. 14).
Studio Accessories and Furniture (Feb. 21).

The Surroundings of the Studio (Feb. 28).
Studio Heating and Ventilation (March 7).
The Postcard Studio (March 14).
The Printing-Room (March 21).
About the Reception Room (March 28).
Home Portraiture (April 4).
Portable Studios (April 11).

COPYING.

THE reproduction of pictures, especially old photographs, miniatures and Daguerreotypes, if properly done, is an important and lucrative branch of the business, especially in studios having a "family" connection. I am sorry to say that all photographers do not think so and therefore do not trouble themselves to do the work properly; as a consequence the jobs do not turn out well, the photographer does not feel justified in charging a decent price, and the customer is not satisfied. He does not always blame the photographer, but concludes that a satisfactory copy cannot be made, and lets it go at that.

The first mistake that most photographers make is to charge less for a copy than for an ordinary sitting. In my experience a copy takes more time in every process than a sitting, and therefore the charge if anything should be greater, at all events not less. The average operator, whether he be proprietor or employee, usually looks on copies as a nuisance to be knocked off at any slack time and then generally after the time promised for delivery, while any special arrangements for doing the work are in many cases conspicuous by their absence. It is a common thing to find an operator copying a c.d.v. pinned on the edge of a background, using the ordinary studio camera and lens. Copies of a sort can be made this way, some quite good, but there is a great loss of time in getting the proper size and in keeping the print and plate parallel. I have seen many a negative made thus in which the image was badly out of shape, instead of rectangular, and only when the print was trimmed was it presentable.

Much time will be saved and better copies turned out if a special apparatus is kept ready for use, and there are few studios so poorly equipped that a camera cannot be found for this purpose. If a camera cannot be spared, at least a pair of runners and a copying board can be arranged so that the studio camera can be used, and if this is a fixture upon its stand the runners and board can be attached to that, in the very simple way invented many years ago by Mr. A. Cowan.

But the copying apparatus is best arranged on a long narrow table which has two strong rails screwed down upon the top. On these slide a platform to carry the camera and the easel upon which the original is fixed. The idea has been carried out in a very neat way in the Southport enlarging table, which is equally adapted for artificial light enlarging or ordinary copying. In this model the easel can be raised and lowered and turned on a pivot so that the image can be quickly got into correct position on the ground glass. It is, however, open to anyone to make a somewhat similar arrangement on as simple lines as may be desired. I would rather work with a couple of slate battens and two grocers' boxes, than fumble about with no proper means of keeping things square.

The camera may be of the simplest type, but it must have fairly long extension; about three times the longest side of

the plate to be used is a useful length. Rising and cross fronts are desirable, as they save moving the original, but a swing-back is unnecessary and even undesirable. A camera which has insufficient extension may be lengthened by the addition of a wooden box or cone; if carefully used, a cardboard extension will answer very well.

The lens should be a non-distorting one, and as an aperture of $f/16$ is large enough for almost all work an expensive instrument is not needed. Any fairly good rapid or wide-angle rectilinear or one of the old triplets of Dallmeyer or Ross or the doublets of the latter maker will all be found satisfactory. Of course, if a modern anastigmat is available, by all means use it, but such good lenses are rarely needed in ordinary studio copying. I have at a pinch used the single lens of a very small Kodak when my bellows extension was not long enough to give the desired magnification with any other lens, and found it quite satisfactory when stopped down.

As a guide to the necessary camera extension for any particular lens, I will venture to repeat the formula for finding the conjugate foci; everyone is supposed to know it, but few remember it when needed. Briefly it is as follows. The distance between lens and original when reducing is the focal length of the lens multiplied by the degree of reduction plus one focal length. The distance between lens and plate is the focal length divided by the degree of reduction plus one focal length of the lens. As an example, reduction to one-third scale when using a nine-inch lens requires four times nine inches or three feet from lens to original and three inches plus nine inches, or one foot from lens to plate. These measurements would be, of course, reversed if we were making a copy three times the scale of the original. By applying the same rule we find that for a copy the exact size of the original we require double the focal length of the lens in use both before and behind it. Much time may be saved by marking the positions for full size, half-scale, double-scale, and any other desired sizes upon the runners of the copying table.

It is useless to expect the best possible results if only plates of portrait rapidity are available. Excellent negatives can often be obtained from good originals, but it is much easier to work with "ordinary" plates for the majority of originals, while "process" plates should always be used for line subjects and very flat and faded silver prints. Some people imagine that orthochromatic plates, with a blue or a yellow filter, are needed for the latter class of subject, but after careful trial I vote in favour of the "process" variety. These have also the great advantage that they can be more easily intensified than ordinary or rapid plates. I am not at all unmindful of the necessity for using orthochromatic or even panchromatic plates for many classes of original, and in most cases the use of a colour screen is a great advantage, if not a necessity. For one thing it minimises the grain, especially

with deep brown or yellowish originals, and it is indispensable with coloured originals, especially when there are blue traperies. Much is claimed for self-screened plates, but for difficult subjects they are not to be compared with an ordinary ortho' plate and a suitable filter. I need hardly say that the filters should be of the modern dyed gelatine type, the old brownish yellow-glass giving very little correction while enormously increasing the exposure.

The exposure of copy negatives calls for a considerable amount of skill, and only those who are constantly engaged on this class of work can make certain of getting the time accurate, yet this is the crux of the whole thing. Much may be learned by making a few strip tests upon various subjects, making a note of the exposure which is judged to be correct, and noting also the time taken to match the tint in an ordinary Bee Exposure meter. At any subsequent time the correct exposure can be found by taking the meter time again and increasing or decreasing the previously noted exposure accordingly. Perhaps an example will help to explain what I mean. Suppose we take an ordinary cabinet print and we find by means of our strip test that with a certain lens aperture and plate, one minute is needed to give a good negative the same size as the original. We find also that the Bee meter exposed to the same light takes ten minutes to match the tint. Then at a later date, wishing to do a similar job, we again use the Bee meter and find that it takes fifteen minutes to reach the tint. This means that we must increase our exposure in like ratio and give a minute and a-half. The colour of the original is an important factor, and more especially the colour of the paper itself. If we have two bromides, one on pure white paper and one on cream toned base, the latter will require at least twice the exposure of the former upon an ordinary plate. In like manner a sepia toned print will need much longer exposure than a black and white if we are to get satisfactory rendering of the half-tones, especially in the shadows.

The lighting of the original should in nearly all cases be strong and direct; very flat and diffused lighting gives flat negatives. We may here take a lesson from the photo-engraver who uses a couple of powerful enclosed arc lamps, one on either side of his copy-board. This not only gives even illumination but minimises any tendency to show the granular texture of the original. For small work a couple of good upright incandescent gas burners will make a very satisfactory illuminant, or a couple of the new small half-watt lamps. The ordinary carbon and metallic-filament lamps give two yellow a light to be good for copying except with ortho plates.

If the exposure be reasonably correct copy negatives require no special care in development, and the developer used for other work will do, with the addition of a little bromide solution. If the progress of development be judged by inspection it is necessary to remember that a copy always starts fairly evenly all over, and to the inexperienced eye would appear to be over-exposed. This should be disregarded and development carried on for the full time, when a bright negative should result.

Great care should be taken of customers' originals, not only with regard to stains and finger-marks, but in the matter of fixing upon the copy board. Never stick a pin through a print or mount which does not belong to you. If drawing pins or push-pins are used the print should be held under the head of the pin and not by the point. Unmounted prints are best copied in a printing frame with a plate-glass front and strong springs, and this is useful also for many very small originals such as prints out of lockets, small ivories and the like, which will not bear having even the slightest part covered up. On no account wet a print or tamper with it in any way without the consent of the owner. For example, an unmounted snapshot which has been carried about and become creased should be dry-mounted before copying, but permission should always be asked.

PRACTICAL.

PROCESSES FOR THE REVERSAL OF A NEGATIVE OR POSITIVE IMAGE.

I.

In many distinct branches of photographic work there is the occasion for the reversal in the same sensitive film of the image, either latent or developed, produced by light. For example, where a number of lantern slides require to be made from drawings or diagrams in books, and only one slide of each is wanted, there is obviously an economy of material if it is possible to produce upon the lantern plate not a negative but a positive of satisfactory quality. In the making of copies, as is now very largely done in installations, such as the Photostat, there is a preference for a positive copy, although the great majority of such copies are negatives, that is to say, in white lines on a dark ground; and a positive, when it is supplied, is usually made by re-copying the negative copy. Another application of the same principle is in the making of an enlarged negative, on a dry-plate or bromide paper, direct from a small one without the intermediary production of a positive transparency. In certain photo-mechanical processes there is likewise a similar demand, as there is also in the business of while-you-wait portraiture. Some few years ago a paper specially manufactured in order to yield a single positive portrait by exposure in the camera was placed on the market, and though it yielded excellent results by a very rapid method of manipulation, did not obtain any substantial market, apparently not from any defect in the material, but from reconstruction of the American firm by which it was made. On these

several accounts there is thus some considerable interest in the processes which have been suggested or worked at one time or another for producing results of this kind, and of which one class is those which obtain by direct development a positive instead of a negative image where a plate or paper is exposed to a subject in the camera, or, on the other hand, a negative instead of a positive image when the material is exposed on an enlarger easel on to which the image of a negative is projected. The second class of process, and by far the greater, is that in which an image is developed in the first instance, and is then dissolved by some solvent of metallic silver, the residual emulsion then being caused to form what may be called a complementary image, that is to say, positive if the original image was negative and vice versa.

The second type of process is one which within the last few years has become familiar from the fact of its use in the Autochrome process, where the original negative image is dissolved by means of the solution of permanganate and acid, and the remaining emulsion, after exposure to light, developed to form a positive. But processes of this kind are of very much older date than the Autochrome process, and include within themselves a considerable number of variations of the same principle. For example, a method, brief instructions for which we have given for many years past in the Almanac, consists in removing the first developed image with a 2 per cent. solu-

tion of ammonium persulphate, afterwards re-developing the remaining emulsion with a developer containing a fair amount of bromide. This is a process which we have frequently used in the past for making a duplicate negative directly, although, of course, when the plate is printed by contact the reproduced negative is reversed as regards right and left, and if printed in the ordinary way yields reversed prints.

In all processes of this kind the differences consist chiefly in the means adopted for removing the first developed image. One of the earliest processes is that of M. Coustet, published in 1905, in which the image is removed by hydrogen peroxide prepared by making up a solution as follows:—

Water	1,000 c.c.s.
Hydrochloric acid	100 c.c.s.
Barium peroxide	50 gms.

This solution, on a negative being immersed in it, dissolves not only the silver image but the gelatine holding it, yielding a plate which bears an image composed of various thicknesses of gelatine and unaltered silver haloid. M. Coustet dissolved out the haloid with hypo, and obtained his reversed image by dyeing the gelatine.

In most of the processes, however, the original image is removed with either bichromate or permanganate dissolved in water, with the addition of acid. A formula recommended by Maes ("B.J.," March 20, 1908, p. 215) for the making of enlarged paper negatives directly consists in developing with amidol, washing out the developer, and exposing for a few seconds to daylight or to an incandescent burner for from 30 secs. to a minute at about a foot distance. The print is then placed in a solution:—

Potass bichromate	15 gms.
Nitric acid	6 c.c.s.
Water	500 c.c.s.

The solution dissolves the silver image and converts the silver bromide into silver chromate. After washing for a considerable time or immersion for a few minutes in a solution of soda sulphite and soda bisulphite, the negative print is developed with amidol to sufficient intensity. Using a similar process, C. R. M. Parr ("B.J.," November 8, 1908, p. 846) employed the following solution for removal of the silver image:—

Potass bichromate	75 grs.
Nitric acid	30 mms.
Water	5 ozs.

The print is subsequently passed through a solution of soda sulphite and potassium metabisulphite, re-developed with amidol, fixed and washed.

This process—of dissolving the acid bichromate and re-developing—was worked out very thoroughly by Douglas Carnegie, who, we know, used it regularly for the making of the large number of lantern slides from book illustrations which he constantly required in his work as a University Extension lecturer. The details which he published of the process are contained in two articles in the "British Journal" of October 23, 1908, p. 811, and July 9, 1909, p. 528. The lantern plates were exposed in the camera glass side towards the lens, and developed film up in an M.Q. developer, using sodium carbonate as the accelerator until the image was clearly visible on the film surface. Development occupied about five minutes. The plate was well rinsed for about one minute and flooded with a reversing solution of:—

Ammonium bichromate	150 grs.
Nitric acid, concentrated	1½ drs.
Water	20 ozs.

The two or three minutes' immersion sufficed to remove the silver image, after which the plate was rinsed for about one

minute, and placed in a black developing dish, to the bottom of which a couple of narrow strips of glass had been cemented so that it could be laid therein film downwards. The previously used developer was poured on, or rather the plate introduced slantingwise into the developer in order to avoid air-bubbles on the surface of the film, the dish rocked for about half a minute, and then about three-quarters of an inch of magnesium ribbon burnt at a vertical height above of it for about three feet. The plate was then left to develop for further five minutes, fixed in an acid fixing bath and washed. In the case of slides from full-tone negatives a weaker light such as that from a flat-flame gas-burner, was found necessary in order to preserve the tones of the negative. If any fog be left on the slide treatment with Farmer's reducer would remove it without reducing the contrast or vigour of the heavier deposits.

The Carnegie process was tested for its practical usefulness by Dr. D'Arcy Power, whose list of the precautions necessary in working it are as follows ("B.J.," March 17, 1911, p. 194):—
1. Expose glass side outwards, so that full development may be obtained without fogging. 2. Develop for greater density than usual in a negative. 3. Wash for from three to five minutes. 4. Turn film side down in a pan of water with a piece of black paper next the film, and remove into full daylight for three to five minutes. 5. Return to dark-room, remove plate, face up, to a bath of ½ per cent. ammonium bichromate acidulated with 1 per cent. nitric acid. In three minutes the image will disappear. 6. Wash in dark-room for fifteen minutes. 7. Re-develop to rather more than required density. 8. Fix in hypo. 9. Should, as is often the case, the surface be soiled by a slight deposit, one much like that on the surface of lots of developing papers, wash over with a little weak Farmer's reducer, and it readily disappears. 10. Wash. The resulting slide should be identical in gradation with the subject. It can be reduced, intensified, or toned like any other lantern-slide.

As regards the exposure to light for re-development, a recommendation of Balagny ("B.J.," August 12, 1910, p. 609) is to make this exposure before dissolving out the primary image on the ground of the silver image protecting the underlying layer of silver bromide and so preventing fog. For protecting the back of the plate during this exposure Balagny squeezed on a non-actinic tissue, then exposing for from one to five minutes in diffused daylight.

Processes in which acid permanganate have been used as the solvent of the first image have been frequently described since the successful employment of this means in the Autochrome process. The very thin film, however, of the Autochrome plate renders reversal a much easier operation than it is with ordinary dry-plates, or even with the more thinly-coated bromid paper. A permanganate formula recommended for Ilford "Smooth Slow" bromide paper by the Rev. F. C. Lambert ("Photographic Scraps," October, 1908, p. 270) is:—

Potash alum saturated solution	2 oz.
Sulphuric acid 20 p.c. solution	1 dr.
Potass permanganate solution	Enough to give the mixture a port wine colour.

The print is developed until the highest light can be fairly seen on the back of the paper, is rinsed, and after treatment in the permanganate bath is passed through a weak solution of oxalic acid to remove any stain. It is then washed for five minutes, laid flat on the bottom of the dish, and exposed to the light of a gas-burner for, say, 30 seconds at one foot. In re-development no image is produced at the end of one minute further exposure is given as required to assist development.

A permanganate formula of G. H. Truman ("The Camera," May, 1910, p. 194) is compounded from a stock bath consisting of 100 grains potass. permanganate in 10 ounces of water

One ounce of this solution is mixed with 10 ounces of water and 1 dram strong sulphuric acid added.

It will be observed that in all these methods a certain nicety is required in exposing the print to light before or after reversal in order to obtain proper re-development of the residual image. A process which dispenses with this uncertainty consists in replacing the re-developer by a solution of sodium sulphide. A method on this basis was worked out by the Eastman Research Laboratory ("B.J.," February 9, 1917, p. 68), apparently in ignorance of the fact that an almost identical process was suggested by W. Morison in "The Bromide Monthly," October, 1908, p. 191. According to Morison, the paper print is developed fully, rinsed in water, and then placed in a bath of chrome alum, after which it is treated in a sulphide solution as used for sepia toning. The sulphide converts the unaltered silver bromide emulsion into silver sulphide, but does not affect the developed silver image. After washing, the developed image is then dissolved out most conveniently by bleaching with a solution of ferricyanide and bromide followed by a hypo bath. The working details of the process published by the Eastman Laboratory differ from those of Morison first as regards the sulphide solution. The latter should be of fair strength, namely, 1 oz. 330 grains of sodium sulphide cryst. dissolved in 32 ounces of water, and preferably with boiling of the solution in order to throw down any iron. The bath should be used at a temperature of 70 degs. F. The solution for the removal of the primary silver image is:—

Potass ferricyanide	11 ozs.
Ammonium sulphocyanide	11 ozs.
Water to	32 ozs.

This very strong bath is applied for from three to four minutes at a temperature from 65 to 75 degs. F., and owing to the solvent action of the sulphocyanide on silver bromide fixes the print as well as removes the silver image.

A process which is something akin to the last one is that of W. L. G. Bennett ("Amateur Photographer," August 24, 1909, p. 181). Here, as in the last-mentioned process, the primary silver image is removed, not by an acid oxidising solution, but by converting it into a compound, which is afterwards easily soluble. Bennett tones the primary silver image in a strong uranium toning bath for five or ten minutes, the object being to convert the silver deposit completely into uranium ferrocyanide. After washing and treatment for one minute in a bath of ammonium sulphocyanide (2 grains per ounce), it is well washed, laid face up in an empty dish, and exposed to the light of an inch or two of magnesium ribbon burnt about two feet distant. It is then re-developed, the alkali of the developer removing the uranium-converted primary image. Obviously the uranium image might be removed with a bath of carbonate of soda, and the residual silver bromide darkened with soda sulphide, thus dispensing with the necessity of exposure to light.

The problem of forming the reversed image from the residual silver bromide is one which has been dealt with in still another way by MM. Lumière and Seyewetz, who, in a paper published in the "B.J.," November 10, 1911, p. 851, record the success

attending the dissolving out of the silver bromide that is left and the re-development of the image which remains with a mercury physical developer or rather intensifier. Their process consisted in developing the original image thoroughly for about four times the usual time, and then in full daylight dissolving the image in a permanganate bath of the composition:—

Potass permanganate	1 gm.
Sulphuric acid, strong	10 c.c.s.
Water	1,000 c.c.s.

The negative is rinsed, cleared with a 2 per cent. solution of soda bisulphite lye, and if not perfectly bleached again passed through the permanganate and bisulphite baths. It is then fixed in a 10 per cent. solution of hypo, thoroughly washed, and the image, which through the exposure to light has been rendered susceptible to re-development, brought up in a solution prepared from the two following stock baths:—

A.—Soda sulphite, anhydrous	180 gms.
Mercuric bromide	9 gms.
Water	1,000 c.c.s.
B.—Soda sulphite, anhydrous	20 gms.
Metol	20 gms.
Water	1,000 c.c.s.

Fifteen parts of A are mixed with 4 parts of B, the reversed image developing slowly in the mixture with freedom from fog.

A variation of this method in which the silver image is not dissolved until it has been used as a kind of screen in exposing the residual silver bromide was also described by Lumière and Seyewetz. In the case of this process the plate is fully developed, rinsed for about a minute, and then placed against a dark ground, such as a sheet of black paper, which is pressed on the glass so that light reaches the emulsion only from the film side. The plate at this stage is then exposed to the light of, say, an incandescent burner for about 10 or 15 mins. at a distance of 20 ins., the silver image then dissolved in the permanganate bath given above, this treatment, as also the subsequent operations, being done by the ordinary dark-room light. The plate is passed through a weak bath of sodium bisulphite, rinsed, fixed in 10 per cent. hypo, thoroughly washed, and the image brought up with the mercury intensifier, made according to the above formula. The intensification is a slow process, occupying from one hour to an hour and a-half, but yields an image of very fine detail and of density equal to that of a negative developed by the customary alkaline method.

In all these processes in which an acid solution of permanganate is employed for the solution of the silver image it is an important point that the solvent bath should be free from chlorides, otherwise the image is partly converted into chloride, and on re-development or other subsequent process will be reproduced as deposit, which fogs what should be the high-lights of the new image and produces an effect worse than a general fog. Commercial permanganate often contains chloride impurity, which can be removed by addition of a few drops of silver nitrate solution to the bath.

ROYAL PHOTOGRAPHIC SOCIETY.—At the meeting of the Society, held on Tuesday, April 8, forty-two members signed their names as members of the newly-formed Scientific and Technical Group.

THE AMAZING MUTES.—Mr. Ward Muir's most entertaining book of the experiences of the members of a touring association in Switzerland has just been issued in a cheap edition, price 1s. 9d. nett, by Messrs. Simpkin, Marshall. Those who did not take our advice, on the book first appearing, to include it among their stand-bys for a long railway journey, should make a note of the cheaper and more compact edition now issued.

TONING VITEGAS PRINTS.—Messrs. Kosmos Photographic, Limited, Letchworth, Herts, send us an eight-page booklet which they have just published on the toning of prints on their Vitegas paper by the hypo-alum and sulphide methods. They give detailed directions for the making and ripening with silver of the hypo-alum bath, and as regards the ordinary sepia papers state their preference for a bleach formula containing a little ammonia. The booklet will certainly be appreciated by those who have any difficulty in these toning methods. A copy may be had on application to the Kosmos Company.

BROMIDE PRINTING, PAST AND PRESENT.

Those amongst us who can remember the early bromide prints which were boomed as the coming process, by Messrs. Morgan and Laing, must be somewhat astonished to find that the crude efforts of those early days have developed into the results of the present day and have almost as effectually wiped out P.O.P. as P.O.P. wiped out the older albumen paper. The advance of bromide has not been without its effect upon other processes; its similarity to platinotype, together with its cheaper rate of production, has had its effect upon the older process and bromide enlargements have also to a very marked extent taken the place of carbon. Very few professionals, now, but do most of their business in bromide. A comparison between the earlier productions in this process and those of to-day undoubtedly show a very marked progress, but it must be admitted that for the last four years there has been very little advance in quality; in fact, there rather seems to have been a retrograde movement. Of course the war has been to blame for this. The paper base has not been up to the old standard, the chemicals have been mostly substitutes, and as such have required much time in experimenting as to their capabilities in place of those formerly in use, and experienced emulsion makers, coaters, etc., have in some cases been called to the colours, so that the wonder is that we have been able to obtain so good an article as we have, even at the terrifically advanced price we have had to pay. However, we may hope that the war is over and that we may look forward to receive better materials and so be able to turn out better work all round. Not only the manufacturers of paper and chemicals have suffered in this manner, through the war, but photographers themselves have lost their best workmen, and have had to rely to a great extent upon unskilled help. No wonder, then, that progress has been slow.

The production of a good bromide print requires, firstly, a good bromide paper, secondly a good printer, thirdly a good developer who can tell a really good result from one that is merely mediocre, and can at once not only diagnose the cause of that mediocrity but can tell how to remedy it. The old tale of the artist and his pupil applies, "What do you mix your colours with?" "Brains, sir, brains." And it is brains that the bromide worker must use in every part of the process. There is also a little something, somewhat akin to brains, and which is known as "Nous"; this is not French for "we," but pronounced "nowse." The first point is to select a suitable paper or card for the negative to be printed. Thus if the negative is exceptionally bright and you have no paper in stock except "vigorous," put that negative on one side until you can obtain some of a softer grade. Should your negative, on the other hand, be soft or lacking in contrast, then the vigorous grade comes to the front; and if not sufficiently bright, there are such things as "gaslight" papers. No photographer should allow himself to be limited to any one grade of paper, for no matter how skilled a man the studio operator may be, the weather often beats him, and he cannot always produce negatives that are all of the same grade any more than he can produce them so that they all require the same exposure. In many instances a negative might produce a better result on matt paper than on glossy, or vice versa, but here the photographer is somewhat handicapped, for the choice so far is mostly made by the sitter, and the only chance is to show a proof on each. A very bad negative is often found to yield a better result on cream paper than on white.

When printing from a very thin negative in a machine, it will be found much better to reduce the strength of the light instead of endeavouring to give a very rapid exposure, as the absolute speed in a case of this kind cannot be accurately gauged, and consequently will vary considerably when a number of prints are required, whereas by a simple manipulation of the gas-tap the time of exposure can be brought within a workable limit. If a large number of prints are required from a negative, the usual test of exposure—viz., the first print—is hardly sufficient to ensure uniformity. A test should be made after at least every twenty pulls, and certainly with every fresh packet of paper or cards opened; the packets may not be of the same batch of emulsion, and it must also be borne in mind that be the illuminant either gas or electricity, neither are unchangeable. An extra light or two put on in the house, or, in the case of gas, a cooking stove or ring being put on makes a great

difference, and even the lighting up in other houses or factories in the vicinity reduces the strength of your printing light. I know of two cases in point. In the one a munition works is close at hand, and directly they light up, the gas at the photographer's diminishes in power 25 to 30 per cent. In the other case, where electricity is the medium, a music hall is in close proximity, and the result of their lighting up is still more marked. It should always be borne in mind that the first aim of a printer is to secure an *exact* exposure and to maintain the exactitude throughout the run; it is not of any use to give a little less or a little more, thinking, or, rather, hoping, that it will all come right in the developer. Such an idea is quite erroneous: the developer may, to a certain extent; force up a slightly under-exposed print, but at the sacrifice of the whites, and an over-exposed one may be stopped when full detail is developed, but at the sacrifice of all pretence of brilliancy; to develop such a print farther produces a worse result. There are some who, in the case of over-exposure, attempt to remedy matters by the use of a highly diluted developer with the addition of bromide; the only result is a print without blacks: what should be black is only of a greenish brown. A true brown can be obtained by abnormal over-exposure and very much weakened developer, plus a much larger quantum of bromide, the process of development in such a case requiring anything from 15 to 30 minutes, according to the brand of paper in use. Perhaps the most generally used developer is M.Q., and even with that there are numerous formulæ. If in doubt which to use, it is perhaps the best policy to take that which is given by the makers of the special brand of paper in use, and if it does not quite come up to expectations, a slight modification may be tried, bearing in mind that excess of hydroquinone tends towards a bluer image, that less hydroquinone and more metal tends to better blacks, while an increase in the carbonate speeds up the action, but has a tendency to induce flatness. On the whole, the M.Q. developer is an easy one to use, keeps for days, and retains its developing power to the last drop; the resultant print is of a pleasing tone of blue black. For the worker who prefers a truer black, amidol is certainly an improvement, but many persons are unable to use this if their skin is tender, or if they have any cuts or scratches on their hands; and as one who has suffered I can assure the reader that amidol poisoning is no joke. Rubber gloves or finger-stalls are a protection, but if much work is to be got through they render the handling of the paper with any speed somewhat difficult. To my mind there is no result that can equal that obtained with the iron developer, but here again there is the drawback that it stains the fingers far worse than either M.Q. or amidol, and stains them black.

While on the subject of developers and developing, I would specially advise the use of a *deep* dish and plenty of developer therein; a very great proportion of the "spoils" are caused by either too shallow a developing dish or too sparse a quantity of developer, either of which is instrumental in producing air bubbles and otherwise affects the even and clean result which should be produced. Too many prints should not be in the solution at once. Many think that the more prints they can cram in the quicker they will get through a given quantity of work, but actual experience has taught me that with, say, twelve prints in the bath at the time it takes no longer to develop, say, 500 than it would do with thirty in the bath at one time, and evenness of development is assured. When turning the prints over, the surface of each one should be carefully examined, and if any trace of a bubble is evident it should be wiped off with the ball of the thumb, and it will be found that if the exposure has been correct the part where the bubble has been will develop up to the same colour as its immediate surrounding; if the print has been over-exposed, well, it would have been a failure in any case. When strengthening the developer in the dish, it should always be done between two batches, never while any prints are immersed, as such a procedure always induces to staining and unevenness; in fact, it is almost impossible to prevent it.

As to rinsing between development and fixation opinions are varied. If the print is transferred direct from the developer to

the hypo-fixing bath, the process of development is at once stopped and the print seems brighter, but necessarily a certain amount of developer is carried with each print into the hypo, which becomes more rapidly deteriorated, and so requires more frequent renewal. On the other hand, if the prints are transferred from the developer into a bath of plain water, that in turn becomes a weak developer, and the developing process is carried on, slowly it is true, but none the less effectively. This may be remedied by making the water slightly acid, but even then too many prints must not be allowed to accumulate in it before transferred to the fixing. As to the fixing-bath itself, I strongly advocate plain hypo, especially where the preparatory wash has been in acidified water, and, with the paper we obtain nowadays, at least twenty minutes' fixing should be given, otherwise brown patches—the result of imperfect fixation—are sure to appear sooner or later, and, unfortunately, mostly later. I say unfortunately because the appearance of these patches will usually occur within a week or two after the prints have been issued to the customer, and so cause trouble and a lot of explanation as to "war conditions," etc., etc. For black and white prints a prolonged

washing is not at all a necessity—in fact, it is rather the reverse where the prints are glossy and have to be enamelled, although for toning by the bleaching process it is absolutely essential that no trace of hypo should be left in the prints.

The various toning processes and hints thereon would take up too much space for the present article, but perhaps a few remarks on the subject of enamelling may not be out of place. For amateurs or small studio businesses the use of powdered talc (or French chalk) for preparing the base is probably conducive to the best results; in larger business, such as local view or trade work, oxgall is certainly preferable from its absolute security against sticking and the speed of the manipulation. The "base" should always be glass, where possible plate, or, failing that, 21 ozs. sheet; both sides may be used, which is, of course, not possible with either ferrotype plates or asphalt-coated blocks, which, while not subject to the danger of breakage appertaining to glass, are far more quickly worn out and done with, so that it will be found, with all the risk of breakage, the glass is still the cheapest in the end, as well as giving the best and brightest glaze.
C. BRANWIN BARNES.

THE FIXING AND WASHING OF PRINTS.

[We find space for the following contribution to the "Photo Era" because it contains data which are very often asked of us by querists, viz., the numbers of prints which can be fixed with a given weight of hypo or, to put it the other way about, the quantity of a hypo solution of a given strength required for the fixation of a certain area of paper. Nevertheless, we are not of the opinion that this is the most advisable direction in which to seek to economise hypo. There are other and more important factors, e.g., temperature and handling, which may easily falsify a rule based on so much hypo for so much paper. On this and other matters referred to in Mr. Stino's paper we have something to say on another page.—EDS. "B.J."]

THE fixing and washing of prints is a subject of much importance. The fixing should receive just as much attention as the washing. Although it appears beyond a doubt that more prints are caused to discolour and fade by improper washing than by improper fixing, there are many that are discoloured by improper fixing.

Many times the print shows both faults—that is, improper fixing and improper washing. Improper washing, in most cases, is due simply to carelessness on the part of the worker. However, improper fixing, although it may be caused by carelessness, sometimes occurs with the most careful worker. In the latter case it is due usually to the worker not being thoroughly acquainted with the various chemicals used in the fixing bath, to the lack of knowledge as to the life of the bath, or to the method of handling the prints while in the bath. It ought to be remembered that prints should be immersed quickly and evenly in the fixing solution, whether or not the short-stop bath is used. The fixing process is very important with regard to the permanency of the prints; therefore it is advisable, for the first few minutes, to keep the prints moving in the bath so as to ensure even fixation.

The prints should be separated occasionally during fixing and allowed to remain in the bath at least fifteen minutes. However, ten minutes in a freshly-made bath will be sufficient if one is attentive to this part of the work and separates the prints at intervals of one minute. It is possible to fix prints in a shorter time than that stated above, but one should not practise this rapid fixing, or sooner or later there will be trouble. A print that is fixed improperly will show this defect usually before reaching the hands of the customer. When sensitive silver-salts are exposed to actinic light, those parts of the print that contain such salts will usually turn pink during the washing of the prints if this work is done in daylight; if not, then the defect will be discovered later during the course of finishing.

One should never use an exhausted bath, as the results obtained will not be permanent. Therefore, if it becomes frothy or soda remains on the surface when the solution is agitated violently, one should discard it and make up a fresh bath. However, a better method to ascertain when the bath has become exhausted is to keep an account of the number of prints that have been fixed in a certain quantity of solution. Then, when the number has been reached that the particular amount of solution has been tested for, one should discard the fixing-bath. This method also tells one that there has been too waste, and this is an important factor in all lines of business.

As stated before, a print that is fixed improperly contains sensitive silver salts which, upon exposure to actinic light, will cause these salts to change to a pinkish tint, the action being slow or rapid according to the amount of sensitive silver contained in the emulsion. It matters not how long or how thoroughly a print may be washed; if there is any sensitive silver contained in the emulsion, those salts will slowly or rapidly change to a pinkish tint. If the print has been washed improperly, one will discover, in the course of time, the appearance of a yellow stain, which gradually causes the image to fade, the action being slow or rapid according to the amount of hypo contained in the print. Therefore, it becomes evident that to make a print as permanent as the paper-stock upon which the image is supported thorough washing is necessary. All the sensitive silver-salts must be eliminated from the print that have not been reduced to a metallic form by the action of the developer. After this has been done it becomes necessary to eliminate thoroughly all the hypo contained in the print so as to ensure its permanency.

A properly compounded fixing bath will answer its purpose for all kinds of developing-out papers. It should contain what is known as a hardener. The hardener is not absolutely necessary for the permanency of the prints, as one can use a plain hypo-bath and obtain prints that are just as permanent as those fixed in a bath to which hardener has been added. The acid hypo-bath is the practical one to use, for the reason that it can be used over and over again until it is exhausted, whereas the plain bath—that is, plain hypo and water—must be made fresh every day; in fact, a new bath must be made up just as soon as it becomes slightly discoloured. If one should ignore the above instructions, the resulting prints will be found to have a yellow stain, either generally or locally.

The plain hypo-bath can be used successfully during the winter months, as all the solutions can be kept at a normal temperature; but during the summer months it is not practicable, for the reason that in warm weather the prints have a tendency to blister and fall. Since there are no chemicals in the plain hypo-bath to overcome this tendency, the bath becomes impracticable—in fact, one should use a plain hypo-bath only when it is absolutely impossible to obtain an acid hypo-bath. This bath is undoubtedly the safest and best to use, for the very simple reason that the various chemicals contained therein preserve the bath until it has been completely exhausted—thereby preserving the colour of the print—and it checks development immediately by placing the print in an acid etate. Moreover, it hardens the emulsion so as to eliminate frilling and blistering.

If the prints have been placed into the fixing solution unevenly there is a possibility of air-bells forming on the face of the print, in which case, if they remain during the fixing period, one will find spots or possibly pinkish spots appearing on the face of the print. This is due to the sensitive silver-salts contained in the parts covered by the air-bells not receiving the action of the hypo. Therefore, the best remedy for this trouble is to separate the prints occasionally in the bath so as to eliminate this fault and to allow even fixation. Again, if one fails to separate the prints properly while they are fixing—even though there are no air-bells—it will be found that the parts where the prints are sticking together do not allow the bath to eliminate the free silver, and again one finds the same result—that pinkish stain. If one should fail to separate the prints properly while they are washing, one will find that in time those parts of the prints will begin to fade away just the same as prints that have been given but a few rinses of water to eliminate all the hypo. Water cannot eliminate hypo from those parts when the prints are adhering tightly together; therefore, be sure to separate all the prints in the fixing-bath and wash waters frequently and very thoroughly.

After the prints have been fixed properly, they should be washed thoroughly so as to eliminate all hypo. This should be accomplished either by the aid of running water for one hour or by twelve changes, allowing the prints to remain in each change for five minutes. It matters not which method of washing is used with regard to the permanency of the prints, provided one turns each print over in the wash-water at least every five minutes during the washing period, and a complete change of water at least every five minutes is made.

Occasionally one will notice dark circular spots on prints while in the sepia bath. These are impossible to remove successfully unless they are exceptionally small. There are many reasons for these marks; but the most common cause is scamping the handling of the prints either in the acid short-stop or fixing-bath. When prints are placed in the bath they must be immersed quickly and evenly so as to obtain even fixing; but if one scamps his work and places the prints carelessly in the solution, face down, there is a possibility of air-bells forming on the surface of the prints and development continuing, thereby causing those parts to be darker in tone, although usually unnoticeable in the black-and-white print. If the air-bell remained during the entire period of fixing, the spot or spots would turn pink upon exposure to actinic light; but in most cases these air-bells are destroyed—in time to fix these parts properly—by the prints being separated occasionally in the bath. As stated above, these spots are not noticeable in the black-and-white print, due to the tone; but are very noticeable after sepia toning, for the reason that sepia tone is lighter and more transparent than the olive black, and those parts under the air-bells are of a deeper sepia tone than the surrounding parts, due to prolonged development. It should be understood clearly that, to avoid this trouble, one should be very careful to keep the prints in constant motion during the first few seconds when prints are placed in the fixing-bath or acid short-stop, so as to eliminate all troublesome air-bells. The diagram illustrates this point.

A = Line of correct development. B = Line of forced development. C = Action of fixing-bath.

The table giving the number of prints that can be fixed thoroughly in sixty-four ounces of bath is based upon the following excellent formula:—

A. Hypo	16 ounces
Water	64 ounces
Dissolve and then add solution B.	
B. Water	5 ounces
Sodium sulphite (dried powdered)	$\frac{1}{2}$ ounce
Acetic acid No. 8	$\frac{3}{4}$ ounce
Alum (powdered)	$\frac{1}{2}$ ounce

One should be very sure to dissolve each chemical in the order given so as to obtain an accurate bath. The fixing bath, as stated before, should be used at a temperature of 65 degrees for summer and winter, although a little variation up or down is permissible.

NUMBER OF PRINTS THAT CAN BE FIXED IN SIXTY-FOUR OUNCES OF HYPO FIXING BATH.

Size of Print.	Number of Sq. Inches.	Number of Prints.
$3\frac{3}{8}$ x $5\frac{1}{2}$	21.31	250
4 x 5	20	266
4 x 6	24	222
$4\frac{1}{2}$ x $6\frac{1}{2}$	27.6	193
$4\frac{3}{4}$ x $6\frac{1}{2}$	30.9	172
5 x 7	35	152
5 x 8	40	133
6 x 8	48	111
$6\frac{1}{2}$ x $8\frac{1}{2}$	55.3	96
7 x 9	63	84
8 x 10	80	66
10 x 12	120	44
11 x 14	154	34
12 x 16	192	27
14 x 17	238	22
16 x 20	320	17
18 x 22	396	13
20 x 24	480	11

It has been found that 64 ounces of hypo and fixing bath will thoroughly fix 250 ($3\frac{3}{8}$ by $5\frac{1}{2}$) cabinet prints; therefore, $3\frac{3}{8}$ by $5\frac{1}{2}$ by 250 is 5,328 square inches of area that will be thoroughly fixed by such a bath.

Problem.—Find the number of 8 by 10 prints that this bath will fix thoroughly.

Solution.—8 by 10 equals 80 square inches in one 8 by 10 print. Bath will fix 5,328 square inches, therefore 5,328 divided by 80 equals 66 prints.

In bringing this article to a close, I should like to impress upon the mind the fact that the thorough fixing and washing of prints is of vital importance to one's photographic business.

GEORGE F. STINE.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Women and Photography.

WOMEN are displacing men as photographic workers. Are they more competent, more suitable, or only cheaper? It is a matter well worth the attention of every photographer, employer or employed.

There was a time when managing, operating, and printing were male prerogatives. While manageresses were few and far between, lady operators and printers simply did not exist. Necessities of war changed all that, and peace finds us with more women than men in responsible positions. This was, of course, expected, but it seems that the ladies are staying, and signs are not wanting that as time goes on their numerical superiority will increase until the day arrives when the male photographer will have become a thing of the past.

War no longer deprives the labour market of men. The R.A.F. alone could supply thousands of skilled photographers were they wanted. The ladies are firmly established. Why?

Let us consider the claims of superiority made for them by many employers. An accomplished photographer is versed in art, chemistry, and mathematics to some extent at least. Besides this, the successful exponent is generally something of a plumber, electrician, and carpenter. Now, although ladies have done well in the various branches of science and art, we have yet to learn that mere man has been equalled or left behind. A perusal of inventors' names will show that. When it comes to the odd jobs so necessary at times on photographic premises—the hurried repair of a machine,

or electric wire, for example—how many competent women workers are there who can still hold their own?

I will be told that odd jobs are not photography. They always were with the male assistant.

Practical efficiency is not everything, however. I have worked with male and female staffs, and must admit that the latter are—or were—the more tractable and long-suffering. I say were; let us look around. Women everywhere are coming into prominence and asserting themselves. The old docility is fast vanishing. Many girls prefer to be out of work rather than take up jobs that once they begged for. Why? Well, to put it brutally, they've "had some," and their future attitude to every job is likely to be the same if conditions and pay are not very good.

The Marchioness of Derry, a keen exponent of the rights of women workers, maintains that men and women should have the same pay for the same output. On the face of it, this is bare justice. If we go to buy a loaf or a grand piano, we don't expect the bill to be less if presented by a woman. Why, then, should we expect to buy work cheaper off a woman? Do lady operators and printers receive men's pay? If so, the argument of superiority is clinched in their favour. If not, they must be poorer workers, or else they are underpaid—in other words, they keep ex-service men out of work by partly giving their own work away.

But perhaps the feminine temperament is more suited to photographic work. With regard to the most important branch—management—it is simply a matter of opinion about which volumes might be said and written without any good being done. As for operating, the ideal temperament is not essentially masculine or feminine. Some studios, houses, and sitters, might prefer a man, others a lady. There is no visible reason why either need be inferior to the other in studio work.

There can be no question, however, of woman's unsuitability for work in the average dark-room. A naval acquaintance of mine who was once a bromide printer describes a submarine as a blankety convalescent home in comparison to the dark-room. I understand there is a girl at present in his old job. Granted that Phyllis or Marie may keep a room cleaner than Tommy or Jack did, it still cannot be denied that woman's constitution is not suited to working in any but the most up-to-date and sanitary dark-rooms, and these are not over plentiful.

There is another kind of suitability for work, dependent on the individual's initiative and thinking capacity, which is often overlooked. A single illustration will explain.

Two rival commercial houses employed men for the "pivotal" and important jobs—operasion, negative making, and enlarging—and girls for mechanical or routine work—"straight" printing, developing by time, etc. Left with one man, one firm refused all important work over and above what he could do. Placed similarly, the other house filled the soldiers' old jobs with girls. At first the latter method seemed to triumph, but the final result is in favour of the other house, which with men back at work has taken up its old reputation and some of their rivals' business as well.

The cause of this was not want of technical efficiency on the girls' part; it was rather due to the male faculty for diagnosing the customers' ideas, which faculty explains the prevalence of men behind lingerie counters, and accounts for hotel diners preferring waiters, who study the diner, to waitresses, who are content to study their technical duties only.

There is a general supposition that female labour is cheaper than male, and if being cheaper means costing less in coin of the realm, there is plenty of evidence in support. But to be cheaper requires more than this. The girl who does a week's work equal in quantity and quality to that of a good man, and does it for the same sum that a Ford packing-case breaker gets per day, is undoubtedly cheap, but this sort of thing won't last. As I have already pointed out, women are waking up; women's unions are appearing in various trades, and female workers are promising to become more independent and arbitrary than males.

When this can be said of photographic employees, perhaps the mere man will come into the field again, but it's quite on the cards that, by then, he will have been squeezed out of the profession—or the country—for good.

THEMIST.

Exhibitions.

CARBON AND OZOBROME PRINTS.

An interesting demonstration of the qualities of carbon and Ozobrome printing is now offered in the exhibition of photographs by these processes which is being held at the Camera Club, 17, John Street, Adelphi, London, W.C. The prints are provided by the Autotype Company, which now, so we gather from a circular, is the manufacturer and purveyor of materials for the Ozobrome process. A very great range of photographic effects shows the corresponding capacity of the carbon process to render in the fullest way the quality in negatives of most diverse subjects. Coming away from the rooms of the Camera Club, one mentally contrasts the beautifully romantic effects in a low key, such as many of those of Mr. Alex. Keighley, or to select an equally fine example, the "Stygian Shore" (No. 22) of Mr. Simmons—as we say, one contrasts these prints with the high-key studies of translucent ice which are shown by the Australasian Antarctic expedition. Nothing, perhaps, could better exhibit the versatility of the carbon process, not only its capacity for tone rendering, but equally its choice of colour appropriate to the subject. The exhibition contains some striking portraiture by Craig Annan, Malcolm Abuthnot, and the Earl of Carparvon. The Ozobrome process is represented by only a few examples, but these show very charming landscape work by its inventor, Mr. Thomas Manly. The exhibition remains open from 11 a.m. to 5 p.m. until April 30, and on April 24 a demonstration of carbon printing will be given at 8 p.m. by Mr. A. C. Braham. Tickets of admission to this fixture may be obtained on application to the Secretary of the club, or to the Autotype Company, 74, New Oxford Street, London, W.C.1.

PHOTOGRAPHS BY THE ROYAL AIR FORCE.

An exhibition of photographs, presented under the title "War in the Air," by the Royal Air Force is now being held at the Grafton Galleries, New Bond Street, London, W. In interest and in the photographic quality of the coloured enlargements it is certainly the finest of the war photographs exhibitions which have been held. Whoever is responsible for "putting on" the exhibition it is evidently someone with a keen sense of the kind of subject which will interest the public. There must have been an immense amount of spade work done in making the selection from the enormous mass of photography accumulated by the R.A.F. Here, however, we see for the first time some of the achievements which have brought about Great Britain's superiority in the air. Perhaps the chief of these, of which a number of photographs are to be found in different parts of the exhibition, is the now famous "hush" ship, the "Furious," with its immense upper deck of size to receive a squadron of aeroplanes and still find room for an airship or so. One of the photographs shows the operation of the tackle employed in raising a machine from its under-deck hangar. There are some striking pictures of the operations of the R.A.F. in Palestine in the shape of prints showing Turkish troops scattering in the hopeless attempt to escape the British airmen's bombs. Some photographs taken obliquely from the air of such well known places as Edinburgh and Trafalgar Square show the great usefulness of such photography for topographical purposes. A note in the catalogue mentions that the enlargements and their colouring again owe their quality to Messrs. Raines and Co., of Ealing. The exhibition remains open until the end of May, from 10 a.m. to 6 p.m. on week days and 2.30 to 5.30 on Sundays. The charge for admission is one shilling, the proceeds going to various charities connected with the R.A.F.

FORTHCOMING EXHIBITIONS.

April 17 to May 22.—Hammersmith Hampshire House Photographic Society Annual Exhibition. Two open classes. Joint secretaries, J. G. Abrahams, 41, Hamilton Terrace, London, N.W.8; A. H. Page, 12, Lime Grove, London, W.12.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, March 24 to April 5.

- MOUNTING.**—No. 7694. Device for fixing cards, photographs, etc., in albums. P. B. Pattison.
- CINEMATOGRAPHY.**—No. 7683. Cinematograph spool. W. J. Arnold.
- CINEMATOGRAPHY.**—No. 7445. Producing moving picture effects for advertising. H. C. Burbridge.
- CINEMATOGRAPHY.**—No. 7942. Shutter for cinematograph film projectors. S. W. Bentley.
- CINEMATOGRAPHY.**—No. 7857. Motion picture machines. M. B. Burgoms.
- CINEMATOGRAPHY.**—No. 7515. Cinematograph projectors. J. A. Eversden.
- CINEMATOGRAPHY.**—No. 7728. Cinematograph, etc., machines. M. Gordon.
- CINEMATOGRAPHY.**—No. 7375. Cinematograph apparatus. H. J. Hinks.
- PRINTING.**—No. 8,373. Photographic printing. F. W. Donisthorpe.
- CINEMATOGRAPHY.**—No. 8,174. Cinematograph projectors. W. Engelke and H. H. Wrench.
- DARK-ROOM LAMPS.**—No. 8,039. Photographic dark-room lamps. J. Hazel.
- CINEMATOGRAPHY.**—No. 8,545. Film-moving mechanism of picture machines. W. E. Minue.
- DEVELOPING TANKS.**—No. 8,600. Developing tanks for photographic films. C. N. L. Pilditch.
- CINEMATOGRAPHY.**—No. 8,595. Carriers for transport of cinematograph films. A. E. Rees.
- CINEMATOGRAPHY.**—Nos. 8,046 to 8,048. Cinematograph cameras. W. C. Vinten.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

LANTERN-SLIDES.—No. 123,892 (May 6, 1918). The invention consists in a lantern-slide, used for announcements, mounted so that it can be raised or lowered vertically in the cinematograph lantern stage. It is raised by a spring drum and lowered by pulling it down by hand. Robert George Elder, of 15, Warton Terrace, Heaton, Newcastle-on-Tyne.

CINEMA-FILMS.—No. 123,842 (March 12, 1918). The invention consists in a film having words, or the letters thereof, progressively impressed near to the mouths of figures as a means of indicating a supposed dialogue. The words may be impressed photographically or from metal type. Samuel Albert Flower, 17, Newnham Road, Wood Green, London, N.

LANTERN SLIDES.—No. 113,150 (February 20, 1917). Two rectangular pieces of glass are selected of exactly the same size. On to one of the pieces of glass are placed three or more single pictures cut from waste cinematograph film. The film pictures, which are placed longitudinally on the glass and a little distance apart, are secured to the glass by narrow strips of black adhesive paper passed across their ends. The second piece of glass is then placed on the top of the pictures and the frame is bound securely together by strips of black gummed paper or tape, or other adhesive material, placed round the four edges.

The advantage claimed for the invention is that the slide thus formed is greatly superior to the present one, as the pictures used will be cuttings from the best quality films, showing excellent photography.—Frederick Winton Perkins, 12, Norton Road, Letchworth, Herts.

FILM SPOOLS.—No. 113,919 (September 19, 1917). The invention has for its object certain improvements in roll films whereby films of one size may be employed in different-sized cameras. In roll-film cameras it is usual to provide markings upon the backing paper for the film, such markings being spaced apart a distance equal to the length of film necessary for each exposure in a camera of a particular size, and showing the number of exposures that have been made. As distinguished from the foregoing, in accordance with the invention the backing for the film is marked in such a manner that a single spool of film of any particular width can be used in any camera made to take films of that width. The divisions on the backing paper are units and sub-divisions of units of length, and enable the user to ascertain the actual length of film used instead of the number of exposures of a predetermined size. The divisions are consecutively numbered and are of known dimensions, 1 centimetre for example. The half centimetre, quarter centimetre, or even smaller dimensions may also be indicated, but not necessarily identified.

The user of such a roll of film would be provided with a table giving names of various cameras in which the spool could be used, and giving against each camera the numbers which should appear at the usual opening or window in the back of the camera, as the successive exposures are made, allowance being made so that there is a division between the exposed portions, and overlapping of the photographs is avoided.—Herbert Nimmo, 44, Kirby Street, Hatton Garden, London, E.C.1.

X-RAY PAPER.—No. 114,933 (June 4, 1917). A sheet of paper or like flexible material previously sensitised in any known manner is coated with a paint or wash of venetian red, chrome yellow, or other suitable preparation which is impervious to light and is easily removable by washing or other similar process. The opaque coating forms protection to the sensitised surface and admits of the paper being handled openly, dispensing with the use of light-tight envelopes and the like, the treated paper being made up in single sheets or in books, packets or blocks containing the desired number of sheets.

For producing a print the prepared sheet or two or more superimposed sheets is supported behind the object to be radiographed, the print being thus taken directly on the paper or a like print on each of the superimposed papers or sheets, which is subsequently washed to remove the opaque coating and develop the print or prints.

By means of the invention, X-ray photographs can be produced with the utmost rapidity, whereby immediate inspection of the finished print is obtainable, this in many cases being of considerable value.—George William Kilner Crosland, New North Road, Huddersfield, and Thomas Pearson Kilner Crosland, Fitzwilliam Street, Huddersfield.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register:—

W. B. DESIGN.—No. 385,673. Photographic chemicals. White Band Manufacturing Co., Limited, 121, Selsdon Road, South Croydon, Surrey; manufacturing chemists.

Analecta.

Extracts from our weekly and monthly contemporaries

Development in the Tropics.

AMIDOL (writes F. Weston in "The Amateur Photographer and Photography" for April 16), owing to the fact that it can be used without an alkali, is specially suitable for developing plates in high temperatures. Any of the standard formulae may be used. Above 80 deg. Fahr. one may get a little fog, but the following developer can, it is said, be used up to 104 deg. Fahr. with good results, both as regards fog and prevention of the melting of the film.

Water	35 ozs.
Amidol or diamidophenol	75 grs.
Sodium sulphite (anhydrous)	7½ drms.
Ammonium sulphate crystals.....	8 ozs.
Potassium bromide	45 grs.

The mixed developer will not keep for more than a few days. The

ammonium sulphate can be replaced by 4½ozs. of anhydrous sodium sulphate. For tank use, it would be necessary to ascertain by actual experiment the times for development at different temperatures.

The plates should go direct from the developer into a hardening-fixing bath. The following is a good one:—

Potassium metabisulphite	150 grs.
Hypo	4 ozs.
Water	20 ozs.
Chrome alum	150 grs.

Dissolve in the order in which they are named.

CROYDON CAMERA CLUB

NOVELTIES and home-made apparatus were to the fore last week, and despite a gloomy forecast by the secretary, the evening proved a complete success. The most welcome novelty, possibly indirectly due to the splendid action of the Liverpool dockers, consisted of the contents of a bottle labelled "whisky," which, divided amongst thirty to forty members, was sufficient to alleviate the feeling of resentment born of recent privations.

Mr. F. Ackroyd showed a bunsen burner converted into a gas fire-lighter. This is connected to the gas supply with a length of the familiar flexible metallic tubing with rubber connectors. Rubber gradually perishes on exposure to light and air, and if the connectors are covered with adhesive black compounded tape (as used for insulating electrical joints) their life will be greatly prolonged. The same idea had occurred to other members, and they congratulated Mr. Ackroyd on his cleverness. Mr. Harpur pointed out that this flexible tubing frequently leaks, which can be prevented by winding round the tape throughout its length without any material loss in flexibility. "Hunt's tape" was alluded to as being excellent. Mr. Ackroyd next showed a beer-warmer, which he said served the purpose of making tea in office hours. This was believed, as he is the antithesis of the beer-warmer type. He remarked that the utensil had a large hole in the bottom, yet had never leaked. Several references being made to "George Washington," he explained that as the hole in the metal gradually formed it filled up with a calcareous deposit. He then passed round the beer-warmer, and those who handled it noticed with considerable dissatisfaction a loose carbonaceous deposit on its outer wall. At this point Dr. Knott, mistaking the office boy for a towel, a disturbance arose.

The Rev. Le Warne was the next star turn, and it can be said with confidence if he is as successful in converting erring humanity to better things as he is in converting apparatus to weird uses he must be a sky-pilot of pristine quality. A handy retouching desk was shown, improvised out of a studio dark-slide, and, like an ex-sinner, capable of backsliding at short notice. The President, Mr. J. Keane, then demonstrated the "Flying Corps" developing tank, a well-designed and solidly constructed apparatus. It permits of the insertion of a thermometer into the developer without admission of light, a really valuable feature. Dr. F. Knott produced several unbreakable glass measures, which were severely tested by members and came through unscathed. Being composed of glass under tension, when they do go only fine dust remains. To those whose habits engender a feeling of uncertainty regarding the position and number of external objects, they should powerfully appeal.

Mr. V. Jobling showed a home-made camera "with all projections flush with the front," a feature believed to be unique; also a folding walking-stick tripod. This and the camera illustrated skill in design and craftsmanship of the highest order. The shutter had its release placed in front, and therefore was actuated by pressure towards the body, an ideal way for minimising any tendency to shake at the moment of exposure. Many others materially contributed to the interest of the evening.

EDINBURGH SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

THE seventh meeting of the session took place on Monday, April 7, Mr. Young in the chair. A letter was read from Mr. Massie, hon. secretary of the Edinburgh Photographic Society, intimating that the proposal to invite the 1920 Scottish Salon to Edinburgh had been discarded owing to the unsettled conditions. He thanked the society for the interest which the members had taken in the matter.

Mr. Young then read a letter from Mr. Sutherland, secretary of the Edinburgh College of Art, intimating that the society's request for the formation of a retouching class had now been granted, on condition that Mr. Young should undertake the tuition personally. This Mr. Young intimated his willingness to do. The class would start in the autumn, and would be held twice weekly, from seven to nine in the evening. Mr. Campbell Harper expressed the society's indebtedness to the president for the manner in which he had pulled this matter through.

Mr. Young then brought up the question of the apprentice. He said that it was now time for the society to formulate a scheme of some definite nature. Letter after letter was being published in the "British Journal" on this question, and, in fact, since he had mentioned the theme in his October address, hardly a week had passed without some contribution of this nature. The P.P.A. merely groped around the subject. The first thing which the photographer could do for his assistant, Mr. Young continued, was to see that he received a proper training, and the beginning of that was an apprenticeship. We lived in different times, and the old conditions no longer held good; and we must have some definite scheme of modified apprenticeship. In two years' time, he pointed out, every assistant under eighteen years of age would be compelled to attend classes during business hours, and the newly-arranged retouching class would then become a day class. He added that he would be glad to hear the views of the members on the subject, and suggested that a committee be appointed to formulate a scheme.

Mr. Johnston pointed out that the public opinion of photography as a profession was anything but a high one, and hence the difficulty of obtaining boys suitable for apprentices. Mr. Young thought that classes of various kinds would greatly help to alter this situation. Mr. Rushbrook felt that this was a matter for all the photographers in Britain. It was pointed out, however, that the onus of making a start would devolve on some small body, and, a lead once given, the idea would spread. The great difficulty which all photographers experienced in giving an apprentice a good knowledge of all the branches was discussed, and it was hoped that by the growth in the number of technical classes the master photographer would be relieved of much personal tuition. A committee, consisting of Messrs. Rushbrook, Campbell Harper, and Johnston, was then appointed to consider the whole question and to make a report.

Mr. Johnston then made his report on behalf of the Exhibition Committee. He gave facts and figures regarding the New Gallery, Shandwick Place. Three weeks would be necessary for the exhibition, one for the purposes of hanging, and the other two for the exhibition. The probable cost for this, including advertising, would be about £60. It was felt that it would be more dignified if the exhibition were not a competitive one, but a competitive class for assistants might be arranged. Mr. Young said that he was anxious to see this exhibition representative of all classes of photography. It was decided to bring the matter up for further discussion.

A scheme of co-operative advertising was then placed before the members, and the details explained. Some nine firms have so far expressed their willingness to enter into this scheme, which promises to be of great benefit to the profession in Edinburgh.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—At the annual general meeting on Monday, April 7, good progress was reported. The president, Mr. W. F. Slater, F.R.P.S., who has worked so hard for the benefit of the society for the past two years, is a well-known figure in photographic circles, and it is with some considerable regret that the rules of the society only permit his occupying that position for the above-mentioned period. As demonstrator and lecturer his services have been much appreciated, and the members present expressed their appreciation. The secretary reported a very successful year's working, with an increase of 33 per cent. in membership. The hon. treasurer reported that the year's working showed a profit, which is gratifying, as the year had been commenced with a balance-sheet showing a slight loss. The following officers were elected:—President, W. B. Ashmole; hon. secretary, Ernest W. Brooks; hon. treasurer, W. F. Slater, F.R.P.S., F.R.G.S.; hon. curator and librarian, L. J. Blake; hon. portfolio secretary, E. C. Perry; hon. excursion secretary, J. Pickwell; hon. lanternist, C. H. Manger; committee—Messrs. Gideon Clark, H. Creighton Beckett, E. R. Bull, C. H. Oakden, Horace Wright, H. Richards, W. H. Howard, W. McEwan, E. W. Taylor, W. E. White, Arnold J. Burt, and E. Gorfin. The new syllabus is now ready, new members are required, and professional workers are invited to join, as this society already includes a good few members of the trade. A copy of the Handbook will be sent free upon application to E. W. Brooks, 4, Ferndale Road, S.W.4. The next meeting at the Central Library is fixed for 7.30 p.m., Wednesday, April 23, when Messrs. Kerotype, Limited, are giving a demonstration of their Kerotype paper.

News and Notes.

LANCASHIRE SOCIETY OF MASTER PHOTOGRAPHERS.—In connection with the exhibition by members to be held at the Art Gallery, Blackpool, on May 27, 1919, the committee desire that specimens submitted should be sent unmounted and *not* framed. The response from members is very satisfactory, but there is ample room for several more photographs. Entries will be in time if received by the hon. secretary up to Monday, April 28.

PHOTO-MICROGRAPHIC SOCIETY.—The next ordinary meeting will be held on Wednesday, April 23, at 7 p.m., at King's College Bacteriological Laboratories, 62, Chandos Street, W.C., when F. Martin Duncan, F.R.M.S., F.R.P.S., will lecture on "The Preservation and Preparation of Microscopic Objects for Photomicrography." Visitors are invited and cards of invitation may be obtained on application to the Hon. Sec., J. G. Bradbury, 1, Hogarth Hill, Finchley Road, Hendon, N.W.4.

PHOTOGRAPHIC FLAME TESTS.—Describing the research now being undertaken by Professor H. B. Dixon in petrol substitutes, the "Times" mentions that an exceedingly interesting and ingenious device used by him is a camera of recording the "spread of the flame" in an explosion. It will take a hundred yards of film photograph a second, and as the film moves at right-angles to the motion of the flame and the lens reduces the image to one-twelfth of the original, it follows that the camera provides a means of analysing a flame travelling at velocities up to 3,000 yards a second. This is an apparatus which Professor Dixon had perfected before undertaking the present investigations.

DEATH OF MADAME LALLIE CHARLES.—The death is announced of Madame Lallie Charles, for many years a well-known society photographer, having her studio and residence in the exclusive Mayfair thoroughfare of Curzon Street. There she conducted a business without any of the outdoor advertisement, in the shape of showcase or window, which even the photographers of Bond Street cannot bring themselves to forgo. Her customers were almost without exception women, and we believe her connection included not only a goodly proportion of London Society, but people of wealth and standing in South America. Some few years ago Madame Charles was the unsuccessful defendant in the lawsuit arising from the building of her Curzon Street studio, as the result of which, and also, so it is stated, of the war upon her business, she became financially embarrassed.

THE LATE ALFRED S. COREY.—We are extremely sorry to have news from New York of the death of Mr. Alfred S. Corey, technical editor of the "Motion Picture News." Mr. Corey was an enthusiastic student of progress in the fields of optics, colour photography and colour cinematography, and during the last few years we have owed to him the opportunity of publishing descriptions of technical advances, particularly in colour cinematography, in the United States which had come under his personal notice. His interest in the technical side of optics and photography was shown by the very valuable résumés of the literature of these subjects which he offered to readers of his paper. It was technical information of a kind which, we may guess, found exceedingly few readers in the American cinematograph industry. Mr. Corey was a large buyer of books from England, and we are asked to remind any booksellers or publishers before whom this notice may come that his affairs are in the hands of Mr. Allison, of Allison and Haddaway, 235, Fifth Avenue, New York, who is taking steps to discharge any of his liabilities.

Correspondence.

- * * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- * * We do not undertake responsibility for the opinions expressed by our correspondents.

THE SECRETARYSHIP OF THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

To the Editors.

Gentlemen,—Will you be good enough to afford the courtesy of publicity in your columns to advise readers who may be members of the Professional Photographers' Association that all communications should now be addressed to the undersigned, who has been appointed by the council honorary secretary for the ensuing twelve months?

S. H. FRY.

5, Highbury Grove, London, N.5.

BRITISH AND GERMAN LENSES.

To the Editors.

Gentlemen,—Referring to the article entitled optical glass, the testimonial of a German photographer to the superiority of British lenses may be of interest. The man in question—one of the most competent professional photographers in the city of Buenos Aires, whom I met there six years ago—was using *r.* Ross-Zeiss; and when I remarked on the fact he confessed that at first he had obtained a "Zeiss" direct from Jena, and, being dissatisfied, had obtained the English lens, which he found far superior. As the formulae of both lenses were identical, the natural inference is that the British firm's system of manufacture—cementing, grinding, etc.—is the more perfect.—Yours faithfully,

CHARLES L. LOWTHER.

Lonsdale Studio, 194, South Lambeth Road, S.W.8.

A COMPLAINT OF ADVERTISERS.

To the Editors.

Gentlemen,—I wish to call your attention to the quite unnecessary delay by photographers in deciding whether goods advertised in the "B. J." and at their request sent them on approval, are suitable or otherwise; also to the considerable delay (I am writing from my own experience) in releasing moneys deposited with "B. J." for such goods sent on approval, and which have not been approved and returned to owner. These are one or two instances:—

On March 6 ult. I sent £7 direct to a firm advertising in the "B. J." for certain photographic apparatus to be sent to me on approval, which duly arrived a day or two after. I returned the apparatus the same day as received by post, it not being what I was looking for. After writing several times, I eventually got back my £7, less cost of carriage, *on the 4th inst.* Accompanying the cheque was a letter: "Your further orders will be much esteemed, and receive our prompt attention."

On March 20 ult. your publisher acknowledged receipt of my deposit of £4 15s. for apparatus to be sent to me on approval from Cambridge, which reached me on the 28th ulto., and not being approved was returned by registered post the next day. It is now the

8th of April, and I am still waiting the return of my deposit, although I paid carriage both ways, and have written the owner three times asking for its release.

Ten days ago I sent a camera on approval by passenger train. On the 4th inst. I spent 1s. 6d. for a pre-paid wire to ascertain this photographer's decision!

Why cannot photographers "get a move on," sirs, and conduct this goods-on-appro. deposit system in a business-like manner, make prompt decisions, accept or return goods quickly, and release deposits quickly? Such delay is not fair to the man advertising the goods, as he may have other applications and other deposits waiting, and may probably lose a sale, entirely owing to these procrastinating ways of doing things.—Yours faithfully,

A BELIEVER IN BUSINESS METHODS.

AERIAL PHOTOGRAPHY IN THE WAR.

To the Editors.

Gentlemen,—In your recent report on the discussion at the Royal Photographic Society on aerial photography, we observed that the name of Flight-Lieut. C. F. Lan-Davis was not mentioned, nor was that of his firm, J. H. Dallmeyer, Ltd., the speakers naturally confining themselves for the most part to reporting those contributions to the art which were within their personal knowledge. We trust you will allow us in the same spirit to put on record that we also had the privilege and fulfilled the duty of supplying many telephoto and other lenses for aerial photography, including our new large Adon and patent lenses, during the war.

We feel sure that Captain Hetherington, if referred to on the subject, would bear us out; and Major Charles W. Gamble, in an interesting lecture, mentioned that a Dallmeyer lens had worked very well in aerial photography, though it does not appear to have been specially prepared for the purpose. We are now enabled to publish an extract from a memorandum by the late C. F. Lan-Davis, F.R.P.S., written in the very early days of aerial photography at the Dardanelles towards the end of 1915, and we may mention that the dark room which he built on Imbros with materials obtained from the sources mentioned in the extract, and from wreckage of a British ship, was in its time among the most important of the extemporised military buildings on that island. The following is the extract from a memorandum of about October, 1915:—

"There were a few stores and tools available, and only by going round personally begging from the 'Ark Royal,' Egyptian Engineers, Maps Office, etc., was I able to get started. I finally succeeded in getting a darkroom built and equipping it. The best method of attachment of the camera to a machine presented difficulties, as the home idea had been to hold the camera in the hand. This was clearly impossible on Morane Parasol machines, where the camera, in order to avoid cutting off, must be on the outside. I arranged a suitable bracket for holding the camera, and proper boxes to hold the plates, and also built on the cameras a direct vision wire finder. The finders sent were of no use, and without one the amount of country included in each photograph and the proper overlapping cannot be at all correctly estimated. I carried out a number of trials in order to find the correct exposure, and, as results of some kind were urgently needed, started work.

"It was immediately apparent that the material supplied from England, though better than nothing, was not at all as good as could be got, and I reported . . . Pilots were advised as to the proper height for flying, and photographic observers trained. The darkroom was got into proper working order and the photographs turned out quickly, and a beginning made with a tracing and filling.

"From plates exposed on one day, clear, bright prints were supplied to the Maps Office by the next day, and in some cases enlargements made. A number of trench and other maps have been made from them, and I may fairly claim that the work turned out is really satisfactory and of use to the General Staff. Observers from the 'Ark Royal' and captains of the monitors have asked for copies of many of the photographs, which they found of considerable value. No. 3 Wing has for long been photographing, but No. 2 Wing results and volume of work turned out compare favourably."

Trusting this will be found an interesting contribution to the history of the modern art of aerial photography in war.—Yours faithfully,

J. H. DALLMEYER, LTD.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

F. N. G.—We have not heard of it coming on the market. Perhaps the patentee, Mr. P. J. Murray, 20, Rutland Park Gardens, Cricklewood, London, N.W., could tell you something about it.

H. P.—The most practical thing to do would be to take a week's course at the Polytechnic, where all the time—five hours a day—could be devoted to practical work. At the end of this time anyone with artistic instincts should be able to work alone.

J. W. I.—Under the Copyright Act of 1911, which came into force June 1, 1912, registration of copyright is no longer necessary. You can learn the modifications in copyright law introduced by the present Act from the manual "Photographic Copyright," issued by our publishers.

G. C.—You should write to the War Trade Department, Central Hall, Westminster, London, S.W. We think it very doubtful if you could obtain a permit, as the special prohibition of the importation of photographic goods from America was re-introduced on March 1 last.

F. J. W.—The only camera of which we have heard specially made for cinematograph portraiture is that of the Bettini Syndicate, Ltd., 17, West 44th Street, New York. Captain Bettini has devised an apparatus by which the moving pictures are taken on a glass plate, and also devices by which any given small picture can be readily shown in an enlarged form. Obviously the small pictures could be taken with any cinematograph camera.

C. W.—If reflected light only is used the lighting will be rather flat, but it will answer to give top light for standing figures. We should fix one lamp in this way so as to give a light to fall at about 45 degrees on the head, one a little lower, say, 2 ft. to one side, and one lower still a couple of feet nearer the background to give a wide light. All the lamps should have calico diffusers. You must consider this as a suggestion only, as the position is somewhat difficult.

S. C.—We do not clearly understand your question; but if it refers to a metallic lustre over the shadow portions of the enlargement, caused by age and exposure to gas fumes, about the only method likely to be of any use is to rub the deposit away with a fairly hard india-rubber. If it is a matt-surface enlargement you might try the effect of rubbing the whole of the surface with flour of pumice, the very finest pumice powder obtainable from artists' dealers. It will do no harm, and it may possibly remove what is usually a very superficial deposit.

J. M.—The plan adopted for making these photographs, and disclosed some twelve or fifteen years ago by its originator, Mr. Newton Gibson, consisted in making the exposure by a few short strands of magnesium ribbon mounted in a holder somewhat in front of the candle, and thoroughly shielded on the side towards the lens. Then, immediately afterwards, the candle was lighted

and a short exposure made of the flame. For this process it is necessary that a black background should be used. You can find a description of this whole process in a volume of the "Photogram," published during the two or three years before 1903, and possibly available at the Newcastle Library.

E. J. P.—1. Certainly, the tank method is the better for a large number of plates, and will give you as good results as dish development if your exposures are reasonably right and you pay attention to having the developer at the required temperature.

2. We advise you to use the developing formulae of the makers of the plates. If you cannot get a tank formula from the makers you will find the ordinary dish formula will answer by diluting with three or four times its bulk of water, and, if it is found necessary on account of stain, by making up the formula with, say, twice the quantity of sulphite. The general practice is to use a developer of such strength that development is complete in from fifteen to twenty minutes.

W. L.—Your arrangement of lamps as sketched should answer very well. The indirect light, reflected from ceiling, will certainly improve the lighting for groups, but we think you should have a 1,000 c.p. lamp for this. We do not think you will always want all the eight 500 c.p. lamps on at once in so narrow a studio, so that it will be wise to have separate switches. We should prefer to have the top row of lamps to raise and lower. For standing figures, 8 ft. 6 in. at 8 ft. does not seem to give a sufficiently high light, and you cannot afford to bring the sitter forward. If you could move the lamps nearer to the background for full length it would be better if it is not possible to raise them.

M. F.—We think you may safely assume that it may be three or four years before you could count upon making a regular income of, say, three or four pounds a week out of Press photography. Portraiture business in a well-populated district such as yours would probably give you a much better return, and more speedily. The Practical Correspondence College will give you ideas as to making news photographs, or rather of thinking of incidents which might be photographed for this purpose. In the ordinary way you do not require a licence, but in many districts photographers who canvass from house to house soliciting orders for photographs and subsequently taking the photographs to the houses are required by the police authorities to have a hawker's licence. Many water companies require photographers to pay for the water by meter.

L. G.—It is impossible to say how much hypo is required for a given number of prints, because so much depends upon the efficiency with which the hypo solution is used in the way of moving the prints in it. The best advice we can give you is to use a bath until, after inserting a slip of dry-plate in it, it takes more than, say, five minutes for the white emulsion to disappear from the plate. If it takes longer you had better throw the bath away. Average strength of bath for bromide prints is 4 ozs. to 20 ozs. of water. Average strength for an alum bath is 2 ozs. of alum in 20 ozs. of water, keeping the prints in solution for from ten to fifteen minutes. We should say that the Rajar M.Q. developer would not require to be double strength for plates. It would, of course, be convenient to make it up of double strength. If you find it gives negatives which are too thin, you can easily use it stronger.

S. A.—1. The Ross 2a lens would be the most suitable one for the enlarging-box. We cannot give measurements without knowing the size to which you want to enlarge. You could take the lens out for other use at any time. (See articles in the "B. J. Almanac," etc., for details of construction). 2. We certainly recommend white blinds in addition to dark ones even with rolled or ground glass. Your builder will, we think, understand how to fit them if you show him the little book. Be sure that he does not place the four wires in one plane. The bottom row of blinds must hang clear of the top row. 3. Your idea of using old backgrounds is quite good, but we should not care for dark grey unless the walls are the same colour. A greyish green would look better with oak slats, and you could easily get ready-made dis-

temper of this or any other colour. The slats may be rather dark oak, 3 ins. wide, $\frac{1}{2}$ -in. thick, and 15 ins. clear between each. If you are going to make square panels you can go up to the level of the eaves, but if only uprights with a rail on top, they should end at 5 ft. to 5 ft. 6 ins. 4. "W.Y.W." means "while-you-wait," and is usually applied to cheap postcard and midget studios.

D. F.—The marks are certainly mysterious, and we cannot say that we have ever seen any like them. The pinhole theory does not seem to us very likely, as presumably the camera was used in the hand, and so not out in strong light in one fixed position for any time. Although it may seem unlikely to you, we should be inclined to look for the cause of the marks in some part of the process after the plate had been exposed. We have seen markings something of this kind which gave a lot of trouble, and were thought to be caused by flare in the lens and bright metal in the camera, but which ultimately proved to be due to finger marks transferred from the back of one plate on to the film of another as they were stacked together awaiting development in the dark-room. We make this suggestion only on the supposition that you have thoroughly overhauled the camera in order to discover any parts of bright metal around the lens mount or near to the shutter which might give rise to an effect of this kind.

T. H.—The only studio gas lamps on the market are the "Howellite" of Messrs. J. J. Griffin and Sons, Kingsway, and the "Powerful" of Messrs. Kodak, Ltd., Kingsway, London, W.C.2. Both of these consist of a battery of some twenty incandescent lamps, in the one case inverted and the other upright. Either can be used with such ordinary gas pressures as 2 in. provided that you have a supply pipe of ample diameter and a meter to correspond. As regards high-power lamps, we do not know that any of them have been used for portraiture, and we think with you that they are only obtainable for compressed gas. You could write to a firm such as Messrs. Falk, Stadelmann, and Co., of Farringdon Road, E.C., who are the largest people in gas lamps in these high powers. In any case, you may be pretty certain that unless the studio is of ample size and very well ventilated the heat from a good size gas installation may easily be unendurable. Except at the cost of enormous heat you certainly cannot get light equivalent to a 5,000 c.p. in half-watt lamps or arcs.

Line Advertisements.

Charges for Insertion.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind the scale of charges. They will thus save themselves delay in the publication of their announcements. A Schedule by which an advertisement can be correctly priced will be sent on request.

Net Prepaid Line Advertisements.

12 words or less	1/-
Extra words	1d. per word.

(No reduction for a series.)

Special Note. Box Number Advertisements.

"Box No." and office address charged as 6 words.
For forwarding replies add 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.
Orders to repeat an advertisement must be accompanied by the advertisement as previously printed.
Advertisements are not accepted over the telephone or by telegram.
The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.
Displayed Adv'ts should reach the Publishers on Monday morning.
The insertion of an Advertisement in any definite issue cannot be guaranteed.

SUMMARY.

In his article this week "Practica" deals with the handling of the studio camera, and considers at length such features as extension, focusing movements, horizontal and vertical swing back and repeating back, which make for convenience and rapidity in use. (P. 215.)

Some hints on the photography of difficult mechanical subjects, such as polished metal articles, and on the effective use which can be made in prints for advertising purposes of photographs taken from a much nearer standpoint, that is to say, upon a larger scale. (P. 217.)

In a contributed article Mr. J. Hall deals with some of the advantages of daylight papers, and instances particular features more or less special to various makes. (P. 218.)

Mr. Albert O. Forrest has the excellent suggestion to make that a fixing bath for bromide prints should contain only so much metabisulphite as to keep the bath free from stain until its fixing powers have become exhausted. (P. 226.)

The British Photographic Manufacturers' Association has adopted a series of standard sizes for small plate cameras, a piece of policy which plainly will affect also, in course of time, the sizes of plates. The new sizes are all in the French metric measures, and it is proposed to designate these, and other small sizes still in use, by numbers. (P. 220.) We have some comments to make on this introduction. (P. 214.)

A large scheme, provisionally introduced by Mr. George Eastman, is planned to make employees of the Eastman Kodak Company and subsidiary companies holders of Kodak shares. Mr. Eastman is offering a large donation for this purpose. (P. 220.)

In forming business partnerships, personal amenability is as important a factor as a proper and formal agreement upon business matters. Both factors should be investigated before a partnership is entered into. (P. 214.)

An exhibition of pictorial photography and of colour transparencies is now open at the Hampshire Home Photographic Society. (P. 222.)

The London Salon is announced to be held, again at the Royal Society of Painters and Water Colours, from September 13 to October 11. (P. 214.)

Some very practical notes on the choice of a lens according to the purpose for which it is to be used are contained in a contribution to "Assistants' Notes." (P. 221.)

A modified pattern of guillotine trimming board is among the patents of the week. (P. 222.)

EX CATHEDRA.

A Word on Intensification.

We constantly hear photographers inquiring for a formula for an intensifier that will bring out undeveloped shadow detail. These do not realise that what they seek is impossible. If such detail as is in the film of the plate is not brought out by development it is lost for ever. Intensification will add to the printing density of the negative, but it cannot bring out in the film what has been never recorded during the exposure or lost through under-development. To our mind, under ordinary conditions, intensification ought never to be needed. A full exposure should be given, and the operator should know his developing agent and the requirements of the printing medium well enough to be able to produce a negative of just the right quality every time. It is only when it is required to add to the density of the negative in order to fit it for another process that intensification should be required, and even then it is quite easy to overdo this latter process and to produce a negative of excessive contrasts. A good plan when requiring some extra printing quality in a soft negative such as is made for contact bromide printing or enlarging, when prints in carbon or other process demanding a more vigorous negative are to be made, is to bleach and sulphide the plate as in sepia-toning prints. The result is that the negative is toned to a sepia which gives a greatly increased printing value. A moderate degree of intensification is obtained without the possibility of spoiling the plate that is always more or less existent with the mercuric processes.

Fixing Bromide Prints.

A very bad practice, which is, unfortunately, very common, is that of allowing too large a number of bromide prints to accumulate in the fixing bath, which is in such cases generally inadequate in size of container and quantity of solution for the amount of work required. The result is that not only is there danger of uneven fixation, no matter how long the prints are immersed, but that there will be an inequality of depth and colour due to the varying times which the prints have been subjected to the action of the hypo. With some brands of paper the difference is very noticeable, while in others it is slight. This can easily be tested by taking out a print after five minutes fixing and leaving another of precisely similar depth in the bath for an hour; better still, let a print be cut in halves and the halves compared after treatment. It takes only a few seconds to remove a proportion of prints from the hypo to a dish of plain water, and this should be done at regular intervals and not only at the end of the batch. When prints are being made in dozens and half-dozens, it is easy to tell from the subjects which prints have had sufficient time. A simpler way is to have two fixing baths,

and to use them successively, when one is full of prints start on the second; when this is full remove the prints from the first dish to the washer and start this again. This obviates the necessity of sorting out the prints and takes very little time indeed as compared with the bad old way.

* * *

Quarter-plates to Go. The memorandum of the British Photographic Manufacturers' Association which appears on another page deals with a matter which has called for a long time for common action by the industry as a whole. There have undoubtedly been too many plate sizes. Their number has grown steadily—perhaps one should say stealthily—as one camera maker or another has thought fit to devise a new size or make a microscopic alteration in an existing one. What with the wide range of British sizes and a similar assortment in metric measurements the plate-maker's register of the dimensions of plates which regularly or at one time or another he is making has grown to unreasonable proportions. We were shown a year or two ago by a maker with whom we were then discussing the matter, his book of plate sizes, and were astounded as much by the variety as by the minute differences which existed in many cases. Such multiplicity is a highly uneconomical factor in a plate works, causing not only extra labour but a considerable waste of material, and therefore it is satisfactory that the Association has announced its policy of making a clean cut among the smaller sizes. It will no doubt raise some qualms that the quarter-plate and the postcard size are among those which are to be displaced, but we imagine—it is in fact suggested—that the change will be gradual and that plates of the abandoned sizes will cease to be made in proportion as the cameras of these sizes disappear. A further point to be noted is that metric sizes have been adopted, a change which will simplify manufacture for the foreign amateur trade. The quarter-plate is to be replaced by one of 8 by 12 cm., the latter a little narrower and distinctly longer, so that its shape is more in accordance with what has been regarded as suitable for the average class of amateur subjects during the past few years. As regards the introduction of a system of identifying each size of plate by a number in place of the specification of its dimensions, we have our doubts. We think that errors are more likely to be made on this system than on the old one, where, if a mistake is made in one figure, the remaining ones suffice to identify the size that is meant. The suggested system unfortunately does not embody this element of security for which, in view of the liability to clerical errors in typewritten indents, there is a real necessity. People can remember names like "vest-pocket" and "quarter-plate," but if they trust to memory in the case of a series of numbers from 0 to 9 they are liable to make mistakes.

The P.P.A. The Council of the Professional Photographers' Association have not done a very wise or discreet thing in letting the announcement of the change in the honorary secretaryship take the form of the brief intimation which appeared in our Correspondence column last week. We do not know what were the causes which have precipitated the change, and we prefer not to speculate in public on the matter. Even assuming that relations had become as strained as the event suggests, it should have been possible to have avoided the sudden rupture and the questions which it arouses. No good, but the reverse, is to be gained by a discussion of the circumstances which have caused Mr. Mackie to disappear from the secretaryship of the Association, which he has held for it must be twenty

years. He was one of the founders of the Association, has been its most thorough-going supporter ever since, and whatever conflict there may have been of late between his own views and that of the Council, a measure of harm has been done to the Association by the precipitate manner of his departure. That is all that we have to say on the incident, and to us it appears all that should be said. The sooner the matter is forgotten the better.

The London Salon. The exhibition arranged by the London Salon of Photography will be held again at the Royal Society of Painters in Water-Colour, 5a, Pall Mall East, London, S.W., from Saturday, September 13, to October 11. The latest day for sending in exhibits has been fixed for Tuesday, September 2. The entry form and prospectus are now in course of being printed and may be obtained on application to the Secretary at the Gallery. Here a reminder may be made to intending exhibitors abroad that the Salon is particularly anxious to secure a representation of current pictorial work from those in distant parts of the British Empire and in non-enemy countries. In the case of such exhibitors the work should be sent mounted but unframed, and it is then prepared for exhibition by the committee in accordance with the plan which has been adopted for some years past—of placing them under glass on the gallery walls.

PARTNERSHIPS.

As it is possible that at the present juncture many demobilised men and others will form the idea of joining their resources with those of another party with a view to commencing in business as photographers, a little seasonable advice may not be without value to those inexperienced in such matters. There are two outstanding questions which have to be satisfactorily settled if any successful co-operation is to be expected. They are the personal character and habits of the parties and the legal conditions of the partnership.

With regard to the first point, it is a melancholy fact that within a few months men who have previously been the best of friends have become bitter enemies, or at least have such strained relations that the position has become almost intolerable. It is therefore necessary that the closest inquiry should be made not only into the general character of a prospective partner, but into his ordinary habits. Perhaps an actual instance may explain more clearly what we mean. Two young men who had met in local circles as members of a cycling club determined to start a small manufacturing business together. The one was a steady, industrious man with first-rate practical knowledge, the other had several years of office experience and was in his way as steady and reliable as his partner. The business man furnished the bulk of the capital, and was entrusted with the task of selling the products of the concern and generally conducting the business management. This would appear to be quite a proper and workable arrangement, but it soon broke down. The capitalist soon took the view that his investment was sufficient to justify irregular attendance at the business premises, and finally the other partner found himself saddled with the job of keeping the books, interviewing customers, and other routine work, with the inevitable result of a compulsory liquidation. In another case a partner caused disaster by overdrafts on the business for private purposes, with the same unhappy result. Further than this, some men, when they find themselves their own masters, develop intemperate and other undesirable habits, which, if they previously existed, were carefully concealed. Unfortu-

nately these traits are not easy to detect in a man one has met at a club, lodge, or even a church, and yet their possibility must be recognised. Even the temperament should be carefully studied, for a touchy man, whose dignity is easily wounded, will not sort well with a jocular partner, nor a slovenly worker with one who is the soul of precision.

To come to the legal aspect of a partnership, there are a few important points to be observed. One is that each member of the partnership is individually liable for the entire debts of the partnership or for any claims or awards which may be made against it. The only way to guard against this is to make the concern a limited liability company, a rather troublesome and costly proceeding. Another point is that the partnership is liable for the acts of any of its members in the way of contracts, agreements, or quotations.

It will therefore be seen that it is very desirable to have a thorough understanding upon all points which are likely to arise before a partnership is entered upon, and this should be embodied in a proper deed, drawn up by a solicitor, and properly stamped. Some points in such a document would be the objects of the partnership and to what sphere its operations are to be limited; the amount of cash, stock, or apparatus to be provided by each party, with the time and manner of its delivery, the duties of each party, with provisos as to holidays, absences, etc., the amount to be drawn by each as salary, and the ratio in which further profits are to be divided, the conditions under which a dissolution of partnership can be claimed by either party, or, in the case of death, the payment based upon the makings of the business and value of the assets to be paid to the deceased partner's estate or to remain as a charge upon the business. The limitations of the individual powers of the parties should also be clearly defined, so that if one exceeds them the other should have proper ground of action against him.

Other points caused by individual conditions would

probably be suggested by the lawyer, and embodied in proper legal phraseology. The ordinary man often laughs at this, and thinks it cumbrous and out of date, but he may find too late that the ordinary loose style of commercial correspondence can often be interpreted in more than one way. Even a Lord Chancellor's will has had to come before a probate court for elucidation; much more therefore may a layman be expected to trip over wording an agreement.

The existence of such a document prevents much discussion and perhaps squabbling after operations have been started, and it can always be referred to if there is any danger of its provisions being ignored. No honourable and reasonable person would object to it, and in itself it furnishes a test as to the bona-fides of the signatories. It is also invaluable in the case of the death of either of the parties. We all know men whom we would trust with our last penny and with whom we could work harmoniously in sunshine or shadow without a written bond, but such men may have undesirable heirs whom perhaps the surviving partner has never seen nor heard of, and when these appear on the scene some such protection is needed.

We have assumed in the paragraphs above that both partners are working in the business, but there is another class, commonly known as sleeping partners, who provide the money necessary for starting a business or some portion of it. These people generally secure themselves against full liability for the debts of the business by becoming "limited" partners, by which means their liability is limited to a certain amount. An agreement is equally necessary in such cases, and our advice is that each party should engage their own solicitors, so that no clause to the detriment of either should be allowed to pass. Very onerous conditions may be imposed without being understood by an unsophisticated person, but which the trained eye of the lawyer would quickly detect.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
The Camera and the Lens (Jan. 10).
Managing the Sitter (Jan. 17).
Backgrounds (Jan. 24).
Studio Exposures (Jan. 31).
Artificial Lighting (Feb. 7).
Printing Processes for Portraiture (Feb. 14).
Studio Accessories and Furniture (Feb. 21).

The Surroundings of the Studio (Feb. 28).
Studio Heating and Ventilation (March 7).
The Postcard Studio (March 14).
The Printing-Room (March 21).
About the Reception Room (March 28).
Home Portraiture (April 4).
Portable Studios (April 11).
Copying (April 18).

HANDLING THE STUDIO CAMERA.

In a previous talk I touched but briefly upon the principal points of the studio camera, without reference to its manipulation, and I will now deal further with the various parts and adjustments of this most important item in the studio.

A studio camera differs from other patterns inasmuch as compactness and portability are disregarded, adaptability to the special purpose for which it is built being the sole point which its designers have in view. Bellows extension is one of the first things to be considered in a modern camera, for it is now the fashion to use lenses of much greater focal length than were in vogue a century ago. For ordinary cabinets a sixteen or eighteen inch lens is commonly used, so that for a camera to be used for nothing larger than half-plates an extension of twenty-two

or twenty-four inches is needed, unless one uses such a lens as the Telecentric, the largest size of which only needs a length of about eleven inches from flange to focussing screen for distant objects, while the equivalent focal length is seventeen inches. For near objects the extra extension needed is the same as for the ordinary type of lens. A safe guide in selecting a camera for a given lens or vice versa is to have the bellows extension about 50 per cent. longer than the equivalent focal length of the lens. This will allow of an image half life-size being obtained, which is now seldom exceeded. A full life-size requires an extension double the focal length of the lens. In cases where extra extension is needed a box front which will slide into the grooves provided for the rising front is useful; while, if it is

made so as to be reversible, extremely short focus lenses may be used as well. Most modern cameras have ample extension without such additions.

Focussing is usually done by rack and pinion, and a screw clamp is often provided to prevent the back from moving when inserting the slide. This indicates the weak point of the racks as usually fitted. If diagonal racks were used there would be little risk of movement. I much prefer the old winch screw system, as with this the handle is always in the same place below the focussing screen, and when you let go of it it "stays put." Moreover, cameras fitted in this way usually have no projecting tailboard, a great advantage with fairly short focus lenses. Another method of focussing, fitted, I believe, to American cameras only, consists of a pivoted lever which moves the camera back an inch or two either way, a screw clamp fixing it when the image is sharp. If greater range is needed it is obtained by sliding the back; the arrangement works smoothly, but comes a little strange to those accustomed to other methods.

The rising front is a simple affair, but for some reason is used by few operators. It is useful for full-length portraits when it is not desirable to tilt the camera too much to place the figure properly upon the plate. The front is usually lifted by hand and secured by a thumbscrew, but it would be a convenience if it could be operated from the rear, as is done with some of the best process cameras.

The swing-backs, horizontal and vertical, are important adjustments, but they should be used with discretion and not brought in unless absolutely needed. It should be remembered that their function on a studio camera is the reverse of their general function in outdoor work. Indoors they are not used to correct the lines, but to bring different planes of the subject into sharp focus without reducing the aperture of the lens. This is always effected at the expense of proper perspective, and when it is possible to obtain sharpness in any other way they should not be used. If we take a sitting figure with the hands in the lap, the latter may be brought into focus either by using a smaller stop or by swinging the top of the camera back outwards. In the former case they appear in proper perspective; in the latter they will be larger in proportion than they should be. The use of modern anastigmats which have a flat field has tempted many people to use the swing as a matter of course. Many of the old portrait lenses had deeply curved fields with very little astigmatism, and these would give uniform sharpness with a sitting figure, even with as large an aperture as $f/3$, without using the swing. No depth is gained by swinging, so that, although the face and hands may be sharp, the waist is usually much out of focus. It is nearly always necessary after adjusting the swing to give a final adjustment to the focus by the ordinary rack or screw, so as to equalise the definition as much as possible.

The swing adjustment is controlled in various ways, the simplest being a clamping screw on one or both sides of the back frame, and this is perhaps as good as any. Most good cameras are fitted with rack adjustments to the swings, but they are liable to work too easily, and if not clamped by a second screw allow the back to shift while inserting the slides. With care this cannot happen, but one is apt to rely upon the rack holding and to forget the clamp. A better adjustment found upon some American cameras is an endless screw working upon a curved rack. This is always holding and requires no clamping, besides being capable of very delicate adjustment. It is altogether the best fitting for the purpose I have used, and British makers would do well to adopt it.

I was recently told that a certain camera which I was handling was not a studio camera because it had no repeating back—that is to say, the slides were arranged for only one exposure in each. This shows the importance some people attach to small details. Certainly most studio cameras are fitted with a repeating movement, so that two exposures may be made

without removing the slide from the camera, but I am not at all sure that the plan is a good one. For one thing, it increases the chance of double exposures, and the slides are made heavier than need be. I much prefer the American plan of one slide, one plate, and of a special fitting made to carry the small slides. It can be only our innate conservatism that perpetuates the clumsy procedure of a focussing screen separate from the slide, a slide shutter which has to be opened, and a lens shutter which has to be closed before the slide can be drawn. For many years the Americans have had the focussing screen and dark slide upon one moving frame, with an arrangement for automatically uncovering the plate, but even they did not complete the arrangement by making the exposing shutter an integral part of the back. This was, however, done some years ago by Messrs. Dallmeyer in an attachment in which the action of pushing the slide into position left everything ready for exposure, so that only the two movements were necessary to make an exposure—namely, sliding the dark slide into position and pressing the rubber ball. For some reason this apparatus has not come into general use, and will probably not do so until the Americans rediscover it and put it on the market again.

With regard to single slides it would be very convenient if they were to be fitted with adjustable bars to take any sized plate instead of loose inner frames. This is common in process cameras, and would be equally convenient for portrait work. This is a fitting place to give a reminder that the velvet slips in the back frame of the studio camera, and also inside the slides themselves, soon get worn or flattened down, and that plates get fogged in consequence. New velvet strips should be fitted at least once a year, and perhaps oftener in busy studios. As many slides as can be afforded should be fitted to the camera, as it is a great saving of time to have at least a dozen plates in the slides at once. One well-known man has a hundred single slides which are all filled when he begins the day's work, and they are replenished as needed. It may seem a big outlay, but such slides need not cost more than ten shillings each by the hundred, and in a big business they would earn their cost in a year.

There are still a few studios where the exposures are made with the old-fashioned cap, but I cannot understand why, as it seems to me that any shutter which would work at all would be preferable. There have been many models of studio shutter on the market, and there is still a good choice. I have tried most, and prefer the simplest, either the single or double velvet flap or the Packard Ideal. The great trouble with most is the rubber release—the ball, tube, and bellows. When new there is nothing better, but when one or the other becomes leaky there is a constant worry. Either the shutter will not open, or if an exposure of more than five seconds is needed the flap begins to drop, and uneven exposure results. Fortunately the Bowden wire or "Antinous" release has solved the problem, and the last objection to the shutter vanishes. It is a good plan to have a long tube or wire, so that when photographing children or animals the exposure may be made while the operator is a good distance from the camera.

Of the studio camera stand there is not much to be said, except that most models do not give sufficient range in height. Anyone who photographs children must feel the desirability of lowering the camera so that he can pose his little sitter on the floor. This is impossible with the ordinary three or four-pillar stand, so that a platform table or other piece of furniture has to be used, but with a two-pillar stand of the Semi-centennial or Hana type the lens can be brought down to less than two feet from the floor, and the work is made much easier. Racks for dark slides are sometimes fitted to studio stands, and are to be recommended, as there is then no running about to pick up another slide during a sitting. Another useful fitting is a clip or pocket to hold the focussing magnifier ready for instant use.

Sufficient attention is not given to shading the camera in

many studios. It is a good plan to have a light frame erected upon the camera stand to support the focussing cloth in such a way that it projects a foot or more over the lens, and a like amount behind the focussing screen. This serves the twofold purpose of shading the lens and of keeping the focussing cloth from dragging the hair, a consideration to the many lady opera-

tors we now have. I have worked in a canopy which ran on wheels on the floor, the camera being inside. No focussing cloth was needed, and it was a luxury to work it. It has, however, the disadvantage that one had either to keep behind the camera all the time or to come outside to make any necessary adjustment of the sitter.

PRACTICUS.

GETTING GOOD PHOTOGRAPHS OF DIFFICULT MECHANICAL SUBJECTS.

[In the paper which we reprint below from "Printers' Ink" some good advice and suggestions are offered to commercial photographers by one who looks at the making of photographs of technical goods from the standpoint of the seller or advertiser.—Eds. "B.J."]

A CERTAIN commercial photographer recently made the remark that he would rather photograph almost anything else than a polished steel ball, which bears out the contention that the simplest mechanical objects are often the hardest to photograph.

That the inoffensive polished steel ball can store up trouble for the photographer and bewilderment on the part of the advertiser who sees the finished print, is attested to by a case which not long ago came under the observation of the writer. It was desired to show a life-size picture of a steel ball about three inches in diameter, and the advertiser insisted upon retaining the highly polished surface as an argument in favour of accuracy and finish.

Accordingly, the ball was carefully polished with chamois to a high degree of brilliancy before being placed in position in front of the camera. The result, as shown by the print, was startling. Every detail of the interior of the studio was faithfully reproduced on the surface of the sphere, including the skylights, furniture, and those who happened to be standing behind the tripod watching the taking of the picture. And directly in the centre of the ball was a dark object which proved to be a perfect miniature of the camera itself. The impression of a steel ball was absolutely lost in the maze of reflections.

A second trial was made by coating the ball with a thin film of putty, but this had the effect of deadening the high-lights and causing the object to resemble the exterior of an egg in texture. Various ways were tried to catch the proper effect without lending an air of grotesqueness, and finally the following method solved the problem:—

The ball was placed on a small pedestal and surrounded with a square frame covered with white cheese-cloth and open at the side toward the camera. The entire camera was then covered with cheese-cloth, a small hole being cut for the lens. This arrangement diffused a pure white light over the surface of the ball, free from reflections, yet preserving the high-lights which the coating of putty had killed. The result was perfectly satisfactory, and brought out the polished surface minus the distortion formerly caused by the reflected image of the studio and its properties.

It may be said here that this simple method of killing reflection is ideal for the photographing of small mechanical objects in general—such as small tools, wrenches, taps, dies, etc., where the problem is to retain polished surfaces without the evil of reflection.

That the method is successful is further proved by the fact that if properly surrounded by cheese-cloth, and the camera properly covered with the same material, it is possible to photograph a large garden globe without catching reflections.

The greatest ally of the camera is the air-brushing outfit, but how generally is it known that for the photographing of small objects a judicious preliminary use of "air" applied to the subject itself will often help to bring out details which otherwise would be lost? For example, the advertiser who

wishes to photograph a watch fob in the form of a medal can many times bring out the design by first squirting on a little air over the surface of the metal. And likewise the practice of chalking the raised name of a machine on a casting will bring out the name strongly in the picture.

These are common tricks of the studio, but the purpose of this article is to place before the reader certain practical points regarding the taking of pictures of difficult mechanical subjects, and preparing these photographs for the copy, rather than to attempt to cover the intricacies of a profession. The usual advertiser is not a photographer, but rather an individual who has in mind certain results, and is often at a loss regarding how best to get them.

When it comes to the taking of shop pictures showing machines at work, it should be remembered that the commercial photographer is rarely a shop man, and hence needs proper direction; not in the matter of *how* to take the picture, but *what* to take. It is the business of a good photographer to study his lights and to calculate the duration of his time exposures rather than to sense the value of some extraordinary heavy cut being taken by a tool.

The truth of this was forcefully brought home to an advertiser of a line of machine tools who secured permission from various users throughout the country to send a photographer to their shops for the purpose of taking pictures of machines in operation. Twenty-five shops granted the request, and a copy of "Bradstreet's" furnished the names of photographers in the different cities. These photographers were written to and told to "get some good pictures of the machines in action."

The results were disappointing in the extreme. From the standpoint of good photography, the pictures were excellent, but almost without exception the views were taken without regard to the value of the work performed. The camera had been set up and the pictures shot with no definite purpose in mind other than to secure a picture of the machine. In many cases the cutting tools were hidden or else the machine was engaged in some freak job inadvisable to advertise. It was obvious that the governing factors had been the direction of the light and the space, rather than an appreciation of the mechanical value of the job and the method by which it was being handled.

Taking this spoiled lot of prints as a guide the concern tried again, using different methods of approach. This time the letters asking permission stated frankly that the photographer who would call was not mechanical, and asked that the company turn him over to the shop superintendent or someone familiar with the work of the machines who could properly direct the picture-taking. The result was a complete reversal of the former experiences, and a valuable quantity of really informative prints was secured. Full particulars regarding the jobs were later secured by sending duplicate prints back to the various shops, with the request that the data be written on the back and the pictures returned.

In preparing shop photographs of this kind for copy, a good lesson may be drawn from the "movies."

Perhaps one of the most appealing tricks of the screen is the "close-up" in order to get the proper emotion across. A scene is flashed showing Marie Bickford standing at the old gate waving a tearful farewell to her lover who is en route to make his fortune in the great city. Marie is too distant to register tears, so a "close-up" is flashed of Marie's face filling the whole expanse of screen and filling the hearts of the audience with her pearly flow of teardrops. Or perhaps the hero receives a telegram. Feverishly he tears it open and then clasps an open palm to his high forehead. What is in it? (We're speaking here of the telegram.) The question is answered by a "close-up" of the sheet telling us that Vivian has eloped with the Count de Varville.

Excellent results along somewhat similar lines, only put to more practical purpose, may be attained in the photographing of machine tools where it is desired to impress the reader with the action of the cutting tools at work on a job, the ease with which the shifting of a lever throws out the gears or the mechanical details connected with some particular part of the machine. As in the case of Marie Bickford, whose distance hides her tears from the close inspection that calls forth the sniffles, so the usual photograph of a machine fails to focus attention on any particular detail, and the point desired to be brought out is hidden in the picture of the machine as a whole.

Right here is where the "close-up" is useful. This "close-up" may be an enlargement of a small section of the big picture, or perhaps it represents another shot, taken at close range, of the cutting tool or detail of the machine to which particular attention is to be called.

In order to get the best effect the "close-up" should be trimmed in the form of a circle and implanted partly on the face of the big picture, encroaching upon the white space to avoid confusion between the two pictures. It is also advisable to define the outline of the circle by a thin band of grey or white where it overlaps the main picture.

Another effective treatment in handling the "close-up" is to bring it entirely outside of the main picture, and carry an arrow down to the section of the machine of which it is an enlargement, in order to tie the idea together and link the close-up to the main photograph.

After a picture has been taken, it usually remains for the retoucher to put on the necessary finishing touches before the engraving can be ordered, and right here exists a degree of misconception in some quarters regarding the way to judge good retouching.

A certain retoucher of exceptional ability who specialises on

retouching photographs of mechanical subjects tells a somewhat amusing incident which illustrates this point. It appears that upon presenting a number of retouched photographs to a client the advertiser found fault with the charges, claiming that the prints did not show much retouching, and consequently the work was not worth the price. And by way of explanation the retoucher was informed that a good retouching job was "laid on thick."

It took some diplomacy to clear away this erroneous standard of valuation, and to convince the advertiser that the retoucher commanded high prices because of the *little "air"* he used rather than the quantity. Almost any dud can smear on a thick coating of Chinese white, but the mark of the expert lies in his knowledge of how *little* retouching to use in order to get the most out of the subject. The gifted retoucher lets well enough alone wherever possible, and uses his air sparingly.

The camera is yet to be discovered which will photograph what is going on inside of a sealed gear box or catch the action of the whirling jets of steam in the heart of a turbine. And yet, for advertising purposes, it is often highly desirable to show the interior workings of a closed chamber—hence the ghost cut.

To execute a phantom view of a difficult mechanical subject properly calls for a display of the highest retouching skill, coupled with some engineering knowledge or leaning toward mechanics. It is customary to have the parts normally unseen and a well-finished job represents no small effort.

The final step in preparing photographs for copy lies in determining the size (unless the size of the finished cut has already been planned for at the time of retouching).

It would appear almost unnecessary to caution care at this stage of the game, when the entire desired effect can be spoiled by ill-considered cropping, but many good photographs have been wrecked on this rock of carelessness. For example, nothing but gross inattention can be responsible for cutting off a machine-tool operator's head just above the eyebrows. Far better to reduce the size of the picture slightly than to crop without regard to anatomy. Better to leave an additional operator out of the picture entirely than to bisect him horizontally.

Readers of technical papers are looking for the picture to tell them just as much as the copy. They are looking for clearness, accuracy of detail and atmosphere. Pictures, to them, are as interesting as the photographs in your newspaper, and a "close-up" of some new tooling method capable of saving time and money does not lack the inspection for which it was created.

See to it that they are not disappointed. A really good photograph is worth all the time and trouble it takes to get it.

R. BRIGLOW LOCKWOOD.

THE MERITS OF GASLIGHT PAPERS.

GASLIGHT papers, in spite of their many alleged shortcomings and disadvantages, are well worth the thoughtful consideration of professionals. After a close study of many of the leading makes I am convinced that they are in many ways superior to, and more useful than bromide papers, and I will do my best to explain my convictions. For ten years I used bromide paper of various makes and kinds, and I had got to believe it was the one and only process; true, it scarce equalled platinum, but it would give a colourable imitation from an inferior negative, and that was good enough, I thought. The depth and quality of carbon was also a bit out of reach, but I considered the other advantages of bromide to outweigh this, and so was satisfied without carbon. Gaslight paper I never thought of, only as a process for tyros, a means of producing multi-coloured prints whose chief properties were blobs and stains; prints which always seemed to shriek out "Pot. brom.," until one day I saw some good gaslight work, which I promptly accused of being carbon! This set me thinking, and I sought a

closer acquaintance, the results of which I set down here for the benefit of any professional who is seeking fresh styles or new effects.

To begin with, let us consider the bad points of gaslight emulsions, after which it will be easier to judge of their merits. The chief disadvantages are low speed, partiality to certain formulæ, poor keeping qualities, small latitude, and liability to stain.

The low speed can be counteracted by the use of a powerful printing light; for instance, Messrs. Kodak's Velox Cabinet uses a mercury tube with which exposures are extremely short, the one tube serving four printers. The partiality to particular formulæ—very often alleged by the makers—is something I never understood. Personally, I find gaslight papers quite as amenable as bromides in this respect, but of that more later. Many gaslight papers do not keep so well as bromides, but if obtained direct from the maker and well stored there is little to fear on that score. The question of latitude is a big one; some makes have very little, and

so require expert handling, as they develop fairly quickly. This means also greater precision on the part of the person developing. This characteristic should mark the paper as one for professional use rather than amateur. Many gaslights, however, have a very great latitude.

The liability to stain is due to insufficient care in handling very often, though certain brands will not stand any forcing. The use of hydroquinone also causes stain occasionally, and in spite of the fact that M.-Q. is the generally used developer for these papers, I have always found amidol give as good—if not superior—results, using only plain hypo for fixing.

To turn to some of the advantages to be derived from the use of gaslight papers. First there is the very low risk of fogging. Instead of working in a dark-room, with only a dim yellow glim, the printer can have a comparatively well-lit room; one or two 16 c.p. globes fixed fairly high will be quite safe. The comparative want of latitude can also be turned to advantage, for not only does it make for greater precision in working, but it means that prints will be good or bad, no uncertainties like bromide gives: "not quite right, somehow, but it will pass." A gaslight print that is not quite right won't pass; the result is that gaslights turned out by professionals will all be good. Another advantage is the quality obtainable from almost any negative. The really perfect bromide print is nearly always from a nearly perfect negative; on the contrary, owing to its ability to produce a false scale of gradation the gaslight emulsion will give a perfect print from a very imperfect negative. It is very necessary, however, to choose the right make and grade of paper; for example, contrast Cyko would be useless for a negative which was too "boney" for bromide, such a negative requiring Velox soft, Gravura No. 1, or Noctona. This latter, as it happens, is not specially intended for hard negatives; nevertheless, it will give fine prints off them if used correctly. For fine results off flat or fogged negatives Wellington's S.C.P. vigorous, Gravura No. 2, or contrast Cyko will surprise; all of these will tone—I find hypo-alum best—the Cyko giving an exceedingly rich Vandyke brown. I do not say it tones better than the English papers (Cyko, I believe, is American), but it is different, and it is among the many differences of gaslight papers that every professional can find something distinctive. The studio out for new effects might with advantage try using "Yto" development paper for contact work, and Wellington's B.B. for enlargements. This would be a distinct remove from the bromide work of an opposition business.

Having said so much for the possibilities of gaslight papers, it will be as well to mention a few of the characteristics of the papers named. The following, it will be understood, are observations made in the actual use of the papers, and may not fully agree with other writings. The developing agent used was amidol, the formula being sulphite 4 oz., amidol 120 grs., water 80 oz. The special formulae given in makers' instructions were also tried with success, though I usually diluted them.

Gravura No. 1.—In the satin surface this is an exceedingly fine paper for portraits. It has a fair amount of latitude, will stand some forcing, and yields good tones.

Gravura No. 2.—One of the two most vigorous papers I ever used. This grade will give bright and luminous results off fogged negatives. It requires careful exposing as the scale of tones alters with over-exposure. Can be used for normal negatives if developer is diluted to balance increased exposure. Both the above yield a very fine colour if plenty of bromide is used.

Velox Soft and Vigorous.—What I have said of Gravura applies also to Velox, though, in my opinion, vigorous Velox requires a rather better negative.

In Noctona we have a gaslight paper of a different sort. To treat this paper as Gravura might lead to disappointment. Noctona will suit a variety of negatives, and will give different results from any one. The rule is, big exposure for contrast, less exposure for softness, the development of contrasty prints being very rapid, so rapid, in fact, that a big saving is realised in developer while the work is merciful to eyes and fingers—less strain and stain. Noctona gives a very pure black and white; for toned prints it requires a decent negative, Noctona gives fine "P.O.P." tones.

Contrast Cyko.—Keeps and works well without any special care, but it requires a hopeless negative. From an extremely thin,

watery affair it will give a first-class print. It is about as vigorous as Gravura No. 2, but slower.

"Yto" Development Paper.—The chief points of this paper are its durability, latitude, and ease of handling. The formulae with which it can be treated are numerous, and it will stand exposures from one to six without spoiling. The makers claim that any colour can be obtained on this paper (from black to brown and red direct), but I have not tried it out so far. The brown-blacks, olives, and dark browns I have obtained, simply by forgetting to time the exposure, were so pleasing that I kept to them. Yto is a stout paper of good quality.

Wellington, Rajar, and Criterion gaslight papers come more or less within my remarks on Gravura; the former two I have only used for pure black and white and sepia; Criterion I have used for olive-black prints.

While papers like Wellington B.B. Rajina and Vitegas are not gaslights, they are worthy of mention as having some points in common. All three will give soft blacks different to anything obtainable on bromide paper. They also give fine shadow effects, and can be used for enlarging with the ordinary bromide enlarging apparatus, giving very superior results. Only a few days ago I saw some Vitegas enlargements which had been hypo-alum toned. They were indistinguishable from first-class P.O.P. directa. Bromides from the same negative were harsh in comparison. Any of the above-mentioned gaslight papers, or any others, can be used for enlarging if a good light source is available. With mercury vapour or daylight and a fairly thin negative the exposure will not be over a minute or two; it may be less. The results are often striking, particularly if the negative is a very weak one. The choice of paper here is even more important than in contact work, and to produce exactly the result one wants, needs some little acquaintance with the paper used.

There are other good gaslight papers beside those I have mentioned. Slogas, for one; but it is manifestly impossible to describe them all. It would take too much space, so I have confined myself to those with which I am most familiar, and trust the reader may find some little bit of useful information herein.

There is just one more point, and that refers back to staining. Forced development and careless fixing sometimes produce yellow and pinky stains. These will nearly always give to weak Farmer's reducer; a dip into hot hypo-alum will also remove them. Overdeveloped prints will sometimes reduce with Farmer's, the result being better than a correctly developed one. I have treated Noctona in this manner to obtain extra vigour.

Overdeveloped and reduced prints, if toned, yield decidedly warmer colours than the usual. J. HALL.

LANCASHIRE SOCIETY OF MASTER PHOTOGRAPHERS.—In making mention last week of the request for prints to be included in the exhibition by members at the Art Gallery, Blackpool, next month, an error was made in regard to the mounting of the prints. These should be sent mounted (not unmounted, as stated), but they should not be framed. The last day for the receipt of entries by the honorary secretary is Monday next, April 28.

A PROFESSIONALS' FIRM.—A firm of manufacturers of professional photographic apparatus which has hitherto marketed its goods only to the wholesale houses, but is now approaching professional photographers directly, is Messrs. Brodrick, of 50, High Street, Charing Cross Road, London, W.C.2. Mr. Brodrick is, as we know, familiar to many professional photographers from the work which he has done in all parts of the country in the way of the design, erection, and decoration of studios and studio premises. In the making of apparatus he has shown himself no less alive to the requirements of the portraiture business. Certain of his specialties, such as the various forms of display table, bromide printer, etc., are no doubt familiar to many readers of these lines. With the conclusion of the war, during which his firm, under unimaginable labour difficulties, has carried out several important contracts for the supply of enlarging easels, developing tanks, and other accessories to the R.A.F., is now turning its energies again to the production of apparatus for professional work. One such, a drying cabinet, is described on another page. Another specialty is a developing tank of particularly good qualities; others are enlarging easels, half-watt installation of a special kind, printing boxes, and studio furniture.

STANDARDISATION IN SIZES OF SMALL PLATE CAMERAS.

The British Photographic Manufacturers' Association has now decided to adopt the following standard sizes in small plate cameras:—

New Size.	In place of
4½ x 6 c.m.	Multitude of small sizes.
6½ x 9 c.m.	3½ x 2½ in. and 6 x 9 c.m.
8 x 12 c.m.	½-plate and 9 x 12 c.m.
10 x 15 c.m.	5½ x 3½ in., 5½ x 3¼ in. and 9 x 14 c.m.

All camera makers are respectfully requested, in their own interests, as well as in the interests of the industry as a whole, to make all their new models in these sizes in preference to the current sizes.

In order to obviate the difficulty of describing sizes by dimensions, the following numbers to designate each size of plate have also been adopted:—

4½ x 6 c.m.	No. 0
6½ x 9 c.m.	No. 1
3½ x 2½ in.	No. 2
4½ x 3½ in.	No. 3
8 x 12 c.m.	No. 4
9 x 12 c.m.	No. 5
5 x 4 in.	No. 6
5½ x 3½ in.	No. 7
10 x 15 c.m.	No. 8
6½ x 4½ in.	No. 9

Thus, a camera constructed to take plates 8 by 12 c.m. would be termed No. 4, and so forth. The trade names adopted by manufacturers can quite well be used in conjunction with the standard numbers as in the following example:—

Nemo No. 2/4 equals model No. 2 in 8 by 12 c.m. size.

Nemo No. A/4 equals model A in 8 by 12 c.m. size.

No manufacturer is asked to discontinue making any of the existing sizes, it being considered that the adoption of the standard sizes for all new models will, in time, render the older sizes obsolete.

TRIPOD BUSHES.

The Association has also adopted the principle that all cameras should be fitted with tripod bushes, either of the two following sizes:—

1. ¼-Whitworth (standard).
2. Continental thread ¼-Whitworth (standard insertion).

The advantages to be derived from standardisation will be obvious to every manufacturer; indeed it is acknowledged to be the prime factor in economical production, and the Association looks with confidence for the support of the whole trade in this progressive movement.

A SHARE-HOLDING SCHEME FOR EASTMAN KODAK EMPLOYEES.

PARTICULARS are given in the Rochester "Post" of April 4 of a large scheme under which employees of the Eastman Kodak will, by sanction of the proprietors of the company, become shareholders.

Nearly 11,000,000 dols. will eventually accrue to the benefit of the employees under this plan just worked out by Mr. George Eastman and the company. Mr. Eastman is to give 6,000,000 dols. worth of stock outright. This stock will be sold at par to employees who have been with the company two years or longer. The proceeds from the sale will be turned into the employees' benefit fund.

Another 6,000,000 dols. will be set aside by the company itself to be sold to the employees at par. The proceeds from this sale will go into the company's treasury. All dividends from the stock will go to the employees who purchase the stock. The proceeds from the sale of the stock given by Mr. Eastman, having been placed in the welfare fund, will be used for the benefit of all the employees, purchasers of stock as well as the others.

The 6,000,000 dols. gift of Mr. Eastman and the 6,000,000 dols. from the company represent the market value of the stock. As time goes on, more and more employees will be entitled to the privilege of purchasing the stock at 100 dols. a share. More than one-half will be permitted to participate immediately. Each purchaser agrees to hold his stock for five years. The stock is quoted on the Rochester Stock Exchange at "591 bid." The present gift to the

employees will not affect the wage dividends, which are to be continued as usual.

The plan was submitted by Mr. Eastman to the directors of the company, who approved of it. In the letter to the directors from Mr. Eastman, published below, the plan is described in full. It is estimated that half a million dollars additional will be distributed among the employees each year at the start, but this will gradually increase as more and more become entitled to part ownership in the company.

The condition that employees hold the stock five years is made because it is the intention to keep these highly profitable shares in the hands of the employees and thereby fully demonstrate to them, over a five-year period, the advantages of receiving dividends from past savings. It is believed that at the end of five years of experience with the stock there will be very few of them who will be willing to sell their holdings.

Provisions are to be made to help those employees who cannot pay for the stock at the time it is allotted, to pay for it through the application of their dividends and other savings. At the present rate of earnings the dividends alone would complete the payment for the stock in from two and one-half to three years. Mr. Eastman has made ample provision for safeguarding the interests of those who for any reason leave the company's employ within the five-year period.

The communication from Mr. George Eastman to the board of directors of the Eastman Kodak company, in which he states his plan for the sale of common stock of the company to employees at par, is as follows:—

"For some time I have had in contemplation a plan for recognising my personal obligation to the loyal wage-earning and salaried employees of this company and its allied companies who have helped to make our business a success. This plan, briefly stated, involves a contribution by me of a substantial amount of common stock to be sold at par to such of the employees above referred to as have shown their loyalty to the company by length of service, the money derived from the sale of these shares to the employees to become a part of a welfare fund to be created for the benefit of all the employees and administered under rules and regulations to be mutually agreed upon by the directors and myself.

"It is my desire to extend the right to participate in the purchase of this stock to those employees still in the service who completed two years or more of continuous service on January 1, 1918, the amount of stock which such employees may purchase to be an amount equal to 2 per cent. of their total wages earned during the entire period of their continuous service before that date.

"The company's records of wages paid to such employees prior to January 1, 1918, indicate that it will require approximately ten thousand shares of common stock to carry out this plan. I wish to donate that stock, but the plan should not end there. It has advantages which are valuable to the company and the present stockholders, and I feel very strongly that the company should make it possible to continue the plan and enable future employees and such of the present employees as cannot participate now, or can participate only partially in the purchase of the above stock, to look forward to the enjoyment of a similar privilege upon a common basis when their loyalty has been shown. This can be done if the company will set aside a portion of its unissued common stock for sale at par to these latter employees, giving to each of them a maximum participation equal to 2 per cent. of wages earned during five years of continuous service.

"Therefore, I make the following offer, viz.:—I will donate sufficient common stock, estimated at ten thousand shares, to enable wage-earning and salaried employees of this company and its allied companies still in the service, who completed two years or more of continuous employment on January 1, 1918, to purchase at par an amount of such stock equal to 2 per cent. of their wages earned while continuously employed prior to that date.

"The above offer is, however, made on condition that this company set aside ten thousand shares of its unissued common stock to be issued for cash at par and made available for sale at par from time to time only to wage-earning and salaried employees of this company and its allied companies, as they attain two years of continuous service, the maximum amount purchasable by any employee to be an amount at par equal to 2 per cent. of the total wages paid such employee during the five years of continuous employment;

with the proviso that an employee entitled to participate on the basis of five years' or more continuous service in the purchase of shares contributed by me shall not be entitled to participate in the purchase of the shares set aside by the company, but an employee entitled to participate to a less extent in the purchase of shares furnished by me may share in the purchase of stock set aside by the company as far as may be necessary to bring his total purchases up to the maximum above stated.

"The stock set aside by the company will enable existing employees who on January 1, 1918, had served continuously two years or more, but not five years, to continue from year to year if they remain with the company their purchase of common shares at par until they have acquired the maximum amount above stated, and will enable existing employees who on January 1, 1918, had not served continuously two years to begin their purchases when they have completed that service, and if they remain with the company to continue such purchases from year to year until they have acquired the maximum amount above stated. It will also for many years to come enable new employees after they have attained two years of continuous service to participate in the purchase from year to year of common stock at par on the same basis and to the same extent.

"If the company, with the consent of the stockholders, shall approve this plan and comply with the above condition the result will be to make available twenty thousand common shares of the par value of 2,000,000 dols. for sale at par to employees of two years' or more standing.

"All of this stock, both that contributed by myself and that set aside by the company, can be distributed to employees most conveniently under the plan above outlined, if represented by certificates of the face value of 10 dols. each, a certificate representing one-tenth of a share of common stock. Such certificates will carry their proportion of dividends paid on the common stock, but the dividends upon certificates may, for convenience, be made payable semi-annually.

"The company should establish a plan to assist employees, whenever necessary, to take up their allotment of certificates and pay therefor in instalments.

"Certificates should be made non-transferable before the date of their maturity, and to avoid having too large a number of certificates mature on the same date they may be issued in two or more series, with different maturity dates for each series, the average maturity period of all certificates being five years from date to issue. As fast as certificates mature they may be exchanged for shares of common stock.

An owner of certificates who leaves the employ of the company for any reason should receive for his unexpired certificates their par value with any unpaid dividends apportionable to them, but in the case of certificates not fully paid for the holder should receive the amount standing to his credit upon his account for the purchase thereof, and in the event of the death or permanent disability of an employee holding unexpired certificates, such certificates should, on full payment being made therefor, be exchanged for stock to be issued to such disabled employee or to the estate of the deceased.

"The interests of the employees in the foregoing respects must be safeguarded by equal representation upon committees formed to deal with all such matters impartially.

"The proceeds of the sale of the shares contributed by me may be used, if necessary, to pay for the shares to be issued by the company for sale to employees; but in that case the money so used must be replaced out of the proceeds of the latter sale, in order that the company's welfare fund may receive ultimately the full par value of the common shares contributed by myself.

"The above is a mere outline of the plan. Many details remain to be worked out and power for this purpose should be given by the stockholders to the board of directors in case the plan is accepted.

"I will hold this offer open until September 1, 1919."

THE BRITISH RED CROSS SOCIETY in a list of persons the value of whose services has been brought to the notice of the War Office includes, we note, the name of Mr. Arthur Payne, of Newcastle, divisional superintendent of the 7th Northumberland Auxiliary Hospital.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

On Buying Lenses.

MORE money is wasted in buying lenses than in the purchasing of any other part of the average photographer's equipment. This must not be taken to mean that an expensive lens is not worth its cost; most usually it is, but owing to lack of care and foresight in selecting the type of lens to be bought, much money is frequently wasted, by paying for qualities in a lens that can never be utilised.

For instance, take the case of the owner of a 12 by 10 stand camera who wishes to use it for general outdoor work, groups, buildings, landscapes, etc. In selecting a lens he may either choose an anastigmat, working at, say, $f/6$, or a "rapid" rectilinear, working at $f/8$. Now, whichever lens he uses he will, in the vast majority of cases, have to stop down to about $f/16$, and at such a stop there will be no discernible difference in the results given by the two lenses, though the anastigmat will probably cost at least three times as much as the other.

It may, therefore, be interesting and helpful to discuss briefly the most suitable lenses to use for various classes of work.

Let us first take the hand camera, as it is a branch of work that is becoming of increasing importance to every photographer. Now, in this class of work almost every exposure made is verging on the "under" side, and it is therefore a great advantage to have a large aperture lens. But it is very little use the average man using a lens of, say, 8 in. focus, and an aperture of $f/4.5$, and expecting to get his negatives in sharp focus. Even with a reflex camera the very small depth of focus of such a lens makes it almost imperative to stop down, and when focussing by scale is necessary it is unusable at its full aperture. The depth of focus is decided, of course, by the absolute, not the relative, diameter of the stop, and it may be taken as a rule that for ordinary hand camera work a diameter of 1 in. is the largest that can be successfully employed. Therefore, on a $4\frac{1}{2}$ in. lens one may use $f/4.5$; on a 6 in., $f/6$; or on an 8 in. lens, $f/8$. Even with these apertures very accurate focussing is needed for near objects, and, so far as this use of the lens is concerned, any excess of aperture over those given may be considered a waste of money.

For reflex work I should put the largest aperture worth paying for at $1\frac{1}{2}$ ins., which will give about $f/5.6$ for the 8 in. lens, the most generally useful focus for half-plate work. The quality of a lens for the hand camera should be of the best, for negatives taken with them will often need to be enlarged, and although the difference in definition of an R.R. and an anastigmat working at $f/8$ may not be noticeable in a contact print, it becomes immediately apparent on enlarging the negative.

General stand camera work.—As a general rule a small stop may be used for this class of work, and therefore a good R.R. lens is as suitable as any other. But as it is in this class of work that a range of foci is most useful, a word or two must be said about convertible lenses. It is, of course, a great economy to obtain three lenses for the price of one, hence the popularity of the unsymmetrical type of convertible anastigmat. But to my mind by far the best system of varying foci is that found in the Cooke and Aldis lenses, where the focus is changed by substituting a new glass in place of the original front glass. By this means a choice of three foci may be obtained at small extra cost, and with the assurance that each focus is given by a completely corrected non-distorting lens.

Portraiture.—For this class of work the great need is speed, and the lack of depth in a long focus lens is no disadvantage. Therefore the choice usually lies between an anastigmat of $f/4.5$ or thereabouts, and a portrait lens. The cost of the anastigmat will be considerably greater, but it has the advantage of being the more generally adaptable lens. Simply for portrait work, however, it has no advantages; in fact the rounded field and less critical marginal definition of the portrait combination are preferred by many workers. In these days it is almost unnecessary to add that whatever type of lens is chosen for portrait work, it should be fitted with an adjustment for diffusion of focus.

For copying, the great thing is to obtain a flat field. This can be

got in an anastigmat at a large aperture, but with other lenses it is only a question of stopping down. In fact, any non-distorting lens may be used successfully for copying. It should be noted, however, that a long focus lens is not very convenient for this work, as it necessitates such a great camera extension, especially when one is copying and enlarging at the same time.

I think that this covers most of the average (photographer's work, with the exception of wide-angle and telephoto work. To take these in order. There are two main types of wide-angle lenses—R.R.s with the largest aperture about $f/16$, and anastigmats, which may have an aperture of $f/6.3$, or larger. In any case, the lens will usually have to be stopped down for exposing, but, especially in the case of dark interiors, the large aperture of the anastigmat is a very great advantage for focussing.

Telephoto lenses may be divided into three classes. First, fixed focus complete instruments, which are nothing more than long-focus lenses with a short back focus; second, variable focus complete lenses, such as the Dallmeyer small Adon; and third, the negative combination to fix behind the usual camera lens. The choice lies between the second and third, and it is entirely a matter of personal taste. But, taken on the whole, the separate negative, used behind a good positive lens, will give the better definition, and allows of a greater range of magnification, as two or three negatives of different foci may be carried.

A. G. WILLIS.

Exhibitions.

HAMPSHIRE HOUSE PHOTOGRAPHIC SOCIETY.

NEITHER a war, nor even a peace, can subdue the indefatigable spirits of the Hampshire House Photographic Society, which has again produced a fine exhibition of pictorial work, hung, unfortunately, under bad conditions of lighting, in the hall of Hampshire House, Hog Lane, Hammersmith. For the benefit of those who may be visiting it, let us say that Hog Lane is a narrow and suspicious looking walled passage a few steps beyond a cinema theatre called the Blue Hall in the main road (King Street) which starts at Hammersmith tube terminus. The narrow passage at its further end leads to the doorway of the garden in which Hampshire House stands. The exhibition is open free each weekday from 4 p.m. to 7 p.m. and on Sundays in the morning and afternoon. It is pleasant to meet again on the walls some old friends, in particular the delicate silvery landscape effects of M. L. Misonne, although we cannot help thinking that in adopting a bluish colour of print M. Misonne has sacrificed much of the charm which characterised his prints when done in a neutral tone. One of them, No. 12, receives a medal. Mr. Louis J. Steele makes a considerable show of his striking work, and receives a medal for "After the Bath," shown at last year's Royal. Other medalled exhibits are "The Seine, Paris," by M. R. Demachy, and "The Combat," by W. G. Hill. A special medal presented by Mrs. C. Atkin Swan goes to a fine little piece of portraiture of an airman, "The Night Hawk," by W. Lee. Among much other work which is distinguished by its pictorial quality is that by Mr. Marcus Adams, Mr. Angus Basil, and Mr. Andrew Barclay, the latter a member of the Hampshire Society. No exhibition, apparently, at Hampshire House is regarded as complete without one or two portraits of the president, Mr. George Hawkings, whose cryptic smile is here seen through the camera of Mr. Walter Benington.

A loan collection includes contributions from Messrs. Fred Judge, John H. Gear, Angus Basil, Marcus Adams, Frederick H. Evans, Alex. Keighley, R. Demachy, and F. J. Mortimer, F.R.P.S. The section devoted to colour transparencies and lantern slides is a large one: in order to view it, application should be made to an attendant for the room to be darkened and the transparencies illuminated by electric light. Altogether the Hampshire House Society may be congratulated upon having once more brought together an exhibition which presents to the people of Hammersmith a very representative collection of modern photographic work. It remains open until May 22.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, April 7 to 12.

REPRODUCTION.—No. 8,735. Photographic reproduction apparatus. A. Cohen.

STEREOSCOPES.—No. 8,800. Stereosopes. J. M. Hattersley.

FILM DEVELOPING.—No. 8,689. Development and chemical treatment of photographic film. C., F. W., and S. M. Portass.

CINEMATOGRAPHY.—No. 9,113. Cinematograph projectors, cameras, etc. J. Salter.

CINEMATOGRAPHY.—No. 9,251. Cinematograph film-feeding apparatus. W. C. Jeapes.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

PRINT TRIMMERS.—No. 123,967 (January 2, 1919). The invention relates to apparatus for cutting or trimming photographs in which the paper is placed on a hinged board, with the edge to be cut projecting between two knives, one of which is fixed to the free end of the hinged board, and the other, provided with an inclined edge, is hinged to the baseboard of the apparatus, and spring-pressed towards the fixed knife.

According to the invention, the fixed knife is secured to the hinged board at right angles to its plane, and with a space between it and the board to allow the edge of the paper to be passed underneath, so as to come between the co-acting blades. By this construction the operator will have an unobstructed view of the paper

placed on the hinged board, and thereby will be able to determine with precision the width of the margin to be left around the picture. Obviously, also, as the shearing blades are arranged practically parallel to each other instead of being at right angles to each other as heretofore, the knives will retain their sharpened edges for a longer period.

In the drawing, which is a side elevation of the trimming apparatus, A represents the baseboard and B the inclined knife hinged thereto; C is the hinged board and D the fixed knife, secured, as shown, approximately at right angles to the board C, and mounted thereon by means of brackets, F, at each end of the board, so as to provide a space, E, between knife and board through which to pass the paper or other material to be cut or trimmed.

The fixed knife, D, may be made of a flat equally thick piece of steel, as shown, or it may be strengthened against the pressure of the spring-pressed knife by making it of angular, pyramidal, wedge, or other suitable shape in cross-section. John Merrett, Trowbridge, Wilts, and Frank Garrett, 15, Dorset Street, Salisbury Square, Fleet Street, London, E.C.4.

CONTINUOUS MOVEMENT CINEMATOGRAPH.—No. 112,488 (January 2, 1917). The image is kept centrally on the screen or plate by means of a prism of annular form, mounted on a drum which is rotated to make one complete revolution during the movement of one picture, the film-moving and prism-rotating mechanism being geared accordingly.

The rotating mechanism is a countershaft E, driven by a suit-

able gear connection *e*, from the film-driving mechanism. On the outer end of the shaft *E* is mounted a drum *F*, having a wide periphery *f*, on which is mounted what may be termed a continuous prism *G*. The prism *G* is formed with a single piece of glass conveniently and preferably, and is such that the central point of any cross-section lies on a circle, and the edge of smallest diameter is slightly spiral, as indicated in Fig. 2, as well as in

Fig. 1 in section. The spiral or volute produces upon the movement of the prism, variable angular dispositions of the operative parts of the prism with reference to planes passing through the axis of the projector.

In the form of the prism, the starting point is shown at *g* while the finish point is indicated at *g'*. The centres of the sections of the prism at these points are the same, as shown at *g'*, so that the refraction of the light-rays is substantially continuous without intermediate jumps or interruptions, the light-rays being gradually passed from one end to the other as the points *g*, *g'* pass the lens. The relative angularity of the different parts of the prism is such as to maintain the proper refraction throughout the upward movement of the picture.

In general operation the prism is placed in front of the lens *D* so that the rays of light passing through the picture and lens *D* pass through the prism and are properly straightened progressively from the entry to the exit of the picture in its passage by the window *C*, as the prism is turned in consonance with the movement of the picture. The prism travels in consonance with the picture strip, and as the film bearing the picture reaches the opening the prism receives the light-rays passing therethrough, and the angular portion of that part of the prism which receives these rays is such that the rays are projected upon the screen. The continued movement of the prism and the picture causes different portions of the prism to be presented to the light-rays, whereby these rays are centered upon the screen irrespective of the position of the picture during its passage by the window. In this way it will be seen that when a picture enters the window the prism is at the starting point *G* and makes one complete revolution while the picture is passing by the window, so that when a succeeding picture reaches the window the angle of the

prism at that time is such that the light-rays are centered upon the screen. William Henry Selby and Frederick Arthur Selby, Kansas City, Missouri, United States.

Analecta.

Extracts from our weekly and monthly contemporaries.

Spring-time Photography.

To preserve the characteristic tonality of grey tree-trunks and the net-work of branches (writes W. S. Davis in "Photo-Era"), a rather short scale of middle-tones must predominate in a picture; consequently, a full exposure should be given whether or not it is deemed essential to employ a ray filter. In many cases, a delicate diffusion of focus seems to help to suggest the soft, vaporous quality of atmosphere so often seen on quiet spring days. There are several ways to obtain this—either in the negative or during printing—without resorting to the use of special soft-focus lenses, although these are quite suitable if at hand. A simple method to obtain general softness in the negative with any ordinary lens is to stop down considerably, and then to rack out the lens beyond the point of sharpest focus until the desired degree of diffusion is seen on the focusing-screen—the size of the stop determines the proportionate amount of diffusion in the various planes of the subject. When printing by contact, one or two sheets of celluloid interposed between negative and paper may be tried. An enlargement, especially upon rough paper, can be given pleasing softness of definition by putting the lens of the enlarger very slightly out of sharp focus. The main point to bear in mind, in all cases, is to suit the mode of treatment to the theme to be expressed. Neither soft-focus nor a sharp image is artistic in itself, although either may be an aid to that end, according to the effect required or the thought to be expressed.

New Apparatus, &c.

The X.L. Drying Cabinet. Made by Messrs. Brodriek, 50, High Street, Charing Cross Road, London, W.C.2.

As we have many times said, the drying of negatives is one of the photographer's operations which has continued to be done without anything like an adequate regard to the exclusion of dust from so delicate a surface as one of wet gelatine or even, for the most part, in the aim to accelerate the drying of the plates. And as regards prints, it is only within the last few years that means have been at all generally adopted for safeguarding prints during the drying process and equally for expediting this latter. Photographers have many of them rigged up cupboards or other receptacles in which prints could be dried in a current of warmed air, but so far as the apparatus manufacturer is concerned the only evidence of his interest in what is a most universal problem has been the introduction of the models of rotary print-dryer, all we believe of American origin. Therefore it was with a good deal of interest that we inspected last week a piece of apparatus which has just been placed upon the market by Messrs. Brodriek for the expeditious drying by artificial heat of both negatives and prints. The apparatus consists of a series of shallow drawers, something in the manner of the sectional type of washer which was introduced some years ago, the bottom of each drawer being formed by crossing tapes. Ten of these drawers, providing a surface of 40 square feet, are mounted in a wooden cabinet so that any one of them can be at once withdrawn, the face of the drawer (on which the handles are mounted) butting against the bar which supports it in the cabinet and also "contacting" edgewise with the fronts of the drawers above and below. The whole front of the cabinet is thus sealed almost as though it was provided with a solid door. On each side the framework of the cabinet is left open, on the right to receive along the surface of each drawer the current of warm air and on the left to discharge this current into a vertical shaft. The air in the model we saw is warmed by a bar gas-burner, although an electrical heater can be had in place of it at the same price. The burner is placed at the foot of a wrought-iron shallow chamber which encloses the right-hand side of the cabinet. Air is thus drawn in and passes with the products of combustion of the gas

over and through the series of drawers on the tapes of which prints or negatives are laid. The burner is, of course, one of the Bunsen type, its blue flame denoting the complete combustion of the gas, and there is no reason to suspect any action upon the prints of the products of combustion. On this point Mr. Brodrick informed us that some delicate tests had been made in a drying apparatus of this same type, but made for the drying of fruit, and no taint from burnt gas could be discovered. When it is remembered that in the ordinary gas oven food

is cooked in an atmosphere which is considerably richer in burnt gases than is that of this apparatus, the idea that prints can suffer anything by a short exposure can be dismissed. The burner consumes comparatively little gas, and we were informed that when the apparatus is kept going all day the cost of gas at 3s. 6d. per 1,000 is only 9d. The apparatus occupies a floor space of about 3 ft. 6 ins. by 20 ins. and is 5 ft. in height. It is nicely made in oak, and in appearance might be mistaken for a cabinet such as many a photographer puts in his studio for the storage of large prints. As regards its speed of drying, we witnessed a test in which some prints wet from the wash water were dried in about fifteen minutes. When, as is usual, prints are first blotted the whole contents of the cabinet, about 230 half-plates, should dry in from twelve to fifteen minutes. The apparatus is one which is evidently the result of most careful design, and we should say that there will be a large demand for it among makers of photographic prints. The price is £16 16s.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, APRIL 26.

Huddersfield Naturalist and Photographic Society.—Lantern Lecture. "Results of Experiments for the Spraying of Potatoes in a Polluted Atmosphere." Mrs. A. S. Bacon, B.Sc.

MONDAY, APRIL 28.

City of London and Cripplegate Photographic Society.—"Practical Intensification and Reduction." N. F. Horne.
South London Photographic Society.—"Impressionists and Past Impressionists." J. Vacy Lyle.

TUESDAY, APRIL 29.

Royal Photographic Society.—"Some English Cathedrals: Ely, Lichfield, Gloucester, and Wells." W. J. Roffer.
Leith Amateur Photographic Association.—"Exposure of Negatives." C. S. McCabe.

Hackney Photographic Society.—Print Competition.
Manchester Amateur Photographic Society.—Sale by Auction.

WEDNESDAY, APRIL 30.

Croydon Camera Club.—Demonstration: "Kerotype." F. W. Kant and T. P. Middleton.

Tunbridge Wells Amateur Photographic Association.—Annual Exhibition.

THURSDAY, MAY 1.

Hammersmith (Hampshire House) Photographic Society.—"More Talk on Lenses and What They Do." W. H. A. Fincham.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, April 15, W. B. Ferguson, K.C., in the chair.

Mr. F. F. Renwick read a paper entitled "Colour Values in Monochrome and a Viewing Filter as an Aid to Obtaining Them." After a preliminary exposition of recent researches on visual sensitivity to colours, in the course of which he gave a résumé of the

most recent experimental data obtained in this field, the lecturer proceeded to deal with the question of the translation of colours into monochrome by means of a colour-sensitive plate and, as was invariably necessary, a light-filter. He laid emphasis upon the two distinct uses to which panchromatic plates, in conjunction with light-filters, were put. In the case of making the selective negatives required in the various processes of colour photography the panchromatic plate was, of course, not employed for a translation into monochrome of the colours of the original but only for recording a certain selection of them. In the case, however, of making a single negative of a coloured subject the aim was to obtain in the negative, or rather in the positive from it, tones which corresponded with the visual perceptions of the colours themselves. If a panchromatic plate and filter were so adjusted that they rendered correctly, say, the visual perception of the spectrum of arc light, the combination would also render correctly that of other continuous spectra—differently, because they were different to the eye. By means of curves in which wave-lengths were plotted against the logarithms of colour luminosities, Mr. Renwick had very ingeniously developed a method of arriving at the absorption properties of filters which were required in order to show visually the effect of using a given filter upon a given panchromatic plate, or, conversely, the properties of a filter, necessary with a given panchromatic plate, for producing a result observed visually through a given filter. He set forth the many difficulties of absorption and permanence of dyes which stood in the way of realising in practice the properties thus theoretically worked out, but he was able to show a series of experimental filters which to a very satisfactory degree corresponded with the theoretical requirements. By means of a colour test-chart projected on the screen the action of these filters was shown, and every user of orthochromatic plates could not fail to be immensely interested in the series of viewing filters which, when used by the eye, for example, in the form of goggles, would show the result of using such-and-such a light-filter with a given colour-sensitive plate, the light-filter itself being used in combination with the glasses. Mr. Renwick further showed the photographic transparencies corresponding with these visual observations of the coloured original, and it was clear that from his experiments the orthochromatic worker should secure a degree of precision in his results which hitherto has been absent. Unfortunately, Mr. Renwick could not hold out any immediate hope that the light-filters would be commercially obtainable.

On the proposition of the chairman the very hearty thanks of the meeting were accorded to the lecturer.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the Council was held on Friday, April 11, 1919. Present: Messrs. Basil, Brown, Chapman, Chaplin, Chase, Chidley, Corbett, Ellis, Fry, Haines, Hana, Illingworth, Lang-Sims, Lankester, Read, St. George, Speaight, Spink, Wakefield, and Watson.

The minutes of the previous Council meeting were read and confirmed. Being the first meeting of the newly elected Council, the Hon. Secretary read the standing orders, and these were confirmed without alteration.

Mr. Lang-Sims informed the meeting that one of their members, Mr. C. F. Dickinson, had recently lost his wife after a lengthy and distressing illness. He moved, and it was seconded and carried:—"That the Council expresses its deep regret at the loss which Mr. Dickinson has sustained in the death of his wife, and offers its sincere sympathy with him in his bereavement."

It was moved by Mr. Frank Brown (Leicester) and seconded by Mr. Reg. Haines (London) that Mr. S. H. Fry be elected hon. treasurer for the ensuing year. The motion having been carried, Mr. Fry stated his willingness to carry on for another twelve months, and thanked the Council for the continuation of the compliment of election to the office.

After a general and somewhat lengthy discussion in connection with the duties of the hon. secretary, it was proposed by Mr. Speaight (London), seconded by Mr. Illingworth (Northampton):—"That Mr. S. H. Fry be appointed to the office of hon. secretary." The motion having been carried, Mr. Fry said he would do his best to carry out this extra duty on the understanding that the Council would relieve him of both his offices at the end of twelve months. He added there would be a lot of work to do, but he would do the best he could.

It was moved by Mr. Gordon Chase (London) and seconded by

Mr. A. Basil (London) and carried:—"That the 'Circular' be continued for the ensuing twelve months, and that the treasurer be authorised to expend £120 thereon."

The Council decided, on the proposition of Messrs. Reg. Haines (London) and A. Basil (London), that the raised subscription should apply to all, including those members who had paid (at the old rate) in advance.

Resolved that Messrs. Alfred Ellis and R. N. Speaight be authorised to sign cheques for and on behalf of the association, and that a copy of the resolution be forwarded to the association's bankers for their information.

A confidential communication from a member in the matter of Whitley Councils was discussed, and the hon. secretary was instructed to make some necessary inquiries. It was stated that no trade (industry) was able to form a Whitley Council unless both sides, i.e., employers and employed, had a trade union or an association. It was proposed by Mr. Brown (Leicester), seconded, and resolved:—"That the hon. secretary obtain from the Ministry of Labour all the information he can on the subject and report to the Council."

The Hon. Secretary reported the receipt of a letter from the secretary of the University Advisory Committee (Y.M.C.A.), Aldershot, asking if the committee could be informed of the necessary training required, and the advantages offered, by professional photography to persons desirous of taking up photography as a means of livelihood. It was agreed to refer the matter to Mr. Marcus Adams, to whom the inquiry was originally made.

CROYDON CAMERA CLUB.

Mr. A. E. FARRANTS demonstrated the beauties of Wanstead Park by means of excellent lantern slides, which set up an almost record rate of oscillation of the lantern-carrier. After the usual graceful allusion to the peaceful reputation of the club, he said he had nothing contentious to offer beyond the statement that Wanstead Park knocked into fits anything in the neighbourhood of Croydon. Few in the club appeared to know where Wanstead held out (such is fame!), but a map showed it to be close to Epping Forest, of which it once formed part. A remark of the lecturer that there was practically nothing between it and the North Pole doubtless accounted for the many winter scenes shown. The famous Wanstead House, dating from early history, has altogether disappeared, a female descendant of the Tilneys being the last holder. She married, but her husband squandered the estate and expired of drink and the usual etcetera, whilst she died of a broken heart. Most pathetic, but, the evening being again "dry," forbade a single tear.

In the discussion Mr. Harpur chided the lecturer for employing some cushion-corner masks, strongly disliked by one who, curiously, has been built on cushion-corner lines. Mr. Reynolds expressed a conviction that Mr. Farrants was an artist, poet, and naturalist in one, an opinion, apparently, based on the slides and not on the lecturer's personal appearance. The president, Mr. Keane, among other complimentary remarks, alluded to the beautiful stuff shown as being at the very backdoor of Croydon.—A most cordial vote of thanks was accorded for a very pleasant evening.

Commercial & Legal Intelligence.

AT THE LONDON BANKRUPTCY COURT on Tuesday, April 15, before Mr. Registrar Mellor, the public examination was appointed to be held of Phillip Ernest Le Poer Power, described in the Receiving Order as F. D. Raymond, late of 7, Queen Square, Bloomsbury, W.C., but upon the case being called on for hearing Mr. J. B. Knight, who attended as Official Receiver, asked that the examination might be adjourned. He explained that the debtor had been bankrupt on three previous occasions, the first in 1893, at Newport, Isle of Wight, when his liabilities amounted to £144,213, and the assets were estimated to produce £9,282, but only realised £1,847. The other two failures were in the High Court of Justice, the first being in 1899, when his liabilities amounted to £34,599. The next occasion was on December 8, 1909, when his liabilities amounted to £25,000. The public examination in both the last-mentioned bankruptcies had been reinstated, and were to take place on June 3 next. Since his previous failure, the debtor had been

interested in a number of companies. In September, 1917, he formed a private company called Colourgraphs, Limited, with a capital of £36,000 in 30,000 preference shares, and 6,000 ordinary shares of £1 each, with the object of acquiring from a Mr. Barron his processes and patents for enlargements in colours from ordinary photographs. Those processes and patents were acquired for £27,000 preference shares and all the ordinary shares. By an agreement with Barron he received from him 9,000 preference shares and 2,000 ordinary shares, and he was to find working capital up to £1,000. As a matter of fact he had probably put into the company about £4,000, which he raised by charging his shares. In November, 1918, he registered another private company called Photocol, Limited, with a nominal capital of £115,000, of which £100,000 was in 10 per cent. preference shares, and £15,000 in ordinary shares. For the purpose of that registration he borrowed £1,000 from a Mr. Soward, which was still owing. The object of the company was to acquire from Barron his patents for the washing and manufacture of photograph plates by a new rotary process. All the shares were to go to Barron with the exception of £16,000 preference shares, which were for the working capital. It was intended to offer to the shareholders of Colourgraphs, Limited, one share in Photocol, Limited, for each share in Colourgraphs, Limited. A provisional contract had been entered into for the purchase by the company of fully equipped works at Thornton Heath, and he hoped to receive from Barron certain ordinary shares for his services. Eventually the examination was adjourned until June 27.

News and Notes.

LANCASHIRE SOCIETY OF MASTER PHOTOGRAPHERS.—At a committee-meeting of the above society held in Manchester on Tuesday, April 15, 1919, it was resolved:—"That this meeting of Lancashire Master Photographers desires to place on record its appreciation of the ready manner in which the plate-makers have dealt with the recent revision of prices, and respectfully to suggest that in all further arrangements the prices of plates and papers be so arranged as to allow to the bona fide professional at least 50 per cent. off list price."

LECTURES ON TECHNICAL OPTICS.—The summer term at the Imperial College of Science and Technology opened on the 29th inst., when the course of lectures on optical designing, computing and testing room methods was continued by Professor A. E. Conrady, A.R.C.S. A special course dealing with the theory and use of both terrestrial and astronomical telescopes will also be given by Professor Conrady, commencing May 1. Polarized light and polarization apparatus are to be fully dealt with—no previous knowledge of the subject being assumed—by Professor Cheshire, C.B.E., A.R.C.S., whose lectures commence on May 2. Mr. L. C. Martin, D.I.C., A.R.C.S., B.Sc., will deliver a course of lectures on colour, commencing May 7. All the fees are nominal.

IMPORTS OF PHOTOGRAPHS.—In the House of Commons on April 14, Sir C. Kinloch-Cooke asked the President of the Board of Trade if he is aware that the restriction of the import of photographs into this country from certain other countries has now been extended to all parts of the world except under special licence; that this is causing some dissatisfaction in art and literary circles, and if he can see his way somewhat to modify the restriction? Mr. Bridgeman: The extension of the prohibition refers to the action taken on March 1, when, as was announced some weeks before, a number of general licences were withdrawn in accordance with general policy, and in this case, as in others, the arrangement existing before the issue of the general licence was reverted to. These restrictions will now be reconsidered in common with other import restrictions in the manner which has already been announced.

NEW RETAIL BUSINESSES.—Complaints are being made (says the "Times") that people who apply for licences to open shops or to take over existing shops from their present tenants have to wait at least three weeks to get the necessary permission. Inquiries show that delay in granting application is not unusual—the period of waiting being sometimes as long as two or three weeks—but this is said to be necessary to avoid hasty decisions which might adversely affect

servicing or recently discharged soldiers and sailors. Out of 43,000 applications for licences which have so far been made 32,000 have been granted, 3,000 have been refused, and the rest are under consideration. Fresh applications are being received to the number of about 2,500 a week.

The administration of the Retail Business (Licensing) Order has recently passed from the Ministry of National Service to the Ministry of Labour. The Order was made during the war to protect the businesses of men called to the colours from competition arising out of the unusual trade circumstances created by the war. It is with that end in view that the regulations have been and still are administered. An official of the Ministry of Labour has explained to a representative of the "Times" that the administration had been decentralised and divided among nine divisions throughout the country. Over 2,000 permissive Orders are issued every week. All applications before refusal are submitted either to a divisional council of the Ministry of Labour, or, in London, to the local advisory committees associated with the employment exchanges. Both the councils and the committees are composed of business men.

When an application is made in London, often by letter, the person desiring to open a shop is sent a form on which certain essential particulars have to be furnished. When the form is returned it is handed to a special investigator for the area. His duty is to visit the premises which the applicant wishes to open, and also businesses of a similar character within a radius of about half a mile to ascertain either whether the owners are absent on military or naval service, or whether the businesses are handicapped by the absence of a serving member of the family. He then reports to the official in charge of the district. The official in turn submits a report to the local advisory committee, a body free from departmental membership which considers the case and recommends the granting or refusal of the application. On their recommendation action is taken.

When a soldier or sailor is demobilised and opens or reopens a business he is given protection for a month or so in order that he may establish himself. Any question of trade competition is completely excluded from the considerations which govern the granting of licences. The Order may not be popular with everybody, but nearly a hundred resolutions have been passed by public bodies pressing for its retention.

INDUSTRIAL RADIOGRAPHY.—An important series of papers on the examination of materials by X-rays will be read at a joint meeting of the Röntgen and Faraday Societies, Tuesday next, April 29, 1919, in the rooms of the Royal Society, Burlington House, London, W.1, from 5 to 7 and from 8.30 to 10 p.m. The chair will be taken by Sir Robert Hadfield, Bart., F.R.S., President of the Faraday Society, who will introduce the discussion.

Professor W. H. Bragg, C.B.E., F.R.S., will deliver an address on "Radiometallography."

Professor Alfred W. Porter, F.R.S., will give short abstracts of the following papers, translations of which will be presented by Sir Robert Hadfield:—

(a) Investigation of metals by means of X-rays. By F. Janus (Munich) and M. Reppchen (Cologne).

(b) The principles governing the penetration of metals by X-rays. By Dr. G. Respondek (Helensee).

Monsieur H. Pilon and Mr. Geoffrey Pearce will give a brief description of the "Apparatus used for Radiometallography," illustrated by lantern slides.

Captain R. Knox and Major G. W. C. Kaye will present a paper on "The Examination of Timber by X-rays."

Sir Robert Hadfield, Bart., F.R.S., Mr. S. A. Main, B.Sc., and Mr. J. Brooksbank, B.Sc., A.R.C.S., will read papers on:—

(a) "Testing the Absorption Power of Different Steels Under the X-rays."

(b) "X-ray Examination as Applied to the Metallurgy of Steel."

(c) "Radiographic Examination of Carbon Electrodes used in Electric Steel-making Furnaces."

(d) "A Method of Testing an X-ray Tube for Definition."

Lt.-Colonel C. F. Jenkin will contribute a note on "The Detection of Hair Cracks in Steel by means of X-rays."

Mr. F. F. Renwick will read a paper on "The Behaviour of Photographic Plates to X-rays Considered in Relation to the Radiography of Metals."

Dr. R. E. Slade will read a paper on "Contrasts in X-ray Photographs."

Monsieur E. Schneider (Le Creusot), President of the Iron and Steel Institute, will present a paper on "Radiometallography."

Professor A. W. Hull, Mr. C. T. Heycock, F.R.S., Mr. A. A. Campbell Swinton, F.R.S., Mr. F. W. Willcox, Captain Leslie Aitchison, Mr. Donnithorne, and others will contribute to the discussion.

Major C. E. S. Phillips will exhibit apparatus used at the War Office X-ray laboratory for testing definition of X-ray bulbs.

Exhibits and demonstrations will also be given by Monsieur Pilon, Messrs. Newton and Wright, Watson and Sons, Cox and Co., and The British Thomson-Houston Co., Ltd.

SUBSTITUTE FOR ACETIC ACID IN THE WET-PLATE DEVELOPER.

To the Editors.

Gentlemen,—I have just received my copy of the Almanac, and I find on page 271 formula for a substitute for acetic acid in the wet-collodion process.

Over 35 years ago I was using for the same purpose the following formula, which I copy from my old notes and send you, as it may prove interesting to your readers. I called it nitro-gelatine developer, and I used no other on wet plates for many years; in fact, I have never changed it.

Stock Solution Nitro-Gelatine.

Gelatine	3 drs.
Water	1 oz.
Nitric acid	1 oz.

Developer (Winter).

Double sulphate iron and ammonia	4 drs.
Nitro-gelatine solution	1 dr.
Alcohol	1 dr.
Water	6 ozs.

Developer (Summer).

Double sulphate iron and ammonia	3 drs.
Nitro-gelatine solution	1 dr.
Alcohol	1 dr.
Water	4 ozs.

Thanking you for the many items of information I have secured from your publication.—I am, yours very truly,

CHAS. LEROY.

1146½, Broad Street, Newark, New Jersey, U.S.A.

THE FIXATION OF BROMIDE PRINTS.

To the Editors.

Gentlemen,—Your article, I am glad to see, "rubs in" the all-important fact that perfect fixation is the thing to strive for.

Obviously, if the silver salts unacted on by light are not rendered completely soluble in the washing water by the efficient action of the fixing-bath, no amount of washing will compensate for the neglect of such a vital point.

As to the question of plain hypo versus acid-hypo, it is rather a counsel of perfection to say that a plain hypo bath is best, but, as we know, its rapid discoloration is against it for professional use.

The objection that an acid-hypo bath will remain clear even after its fixing properties are seriously diminished is a well-founded one.

Personally I consider the amount of metabisulphite usually recommended for addition to the hypo is excessive, in that it tends to prolong the clear state of the bath up to the time when the power of the fixing agent (hypo) is considerably weakened. Some years ago I made a few experiments to find how much metabisulphite was required to keep the bath clear for only as long as it was active in its fixing properties. Varying amounts of metabisulphite were tried

and the fixing powers of the bath tested with unexposed plates in the usual way, with the result that I have for a long time used about one-quarter of the metabisulphite usually prescribed.

To take an example: One well-known maker of bromide paper gives a formula—hypo, 18 oz.; water, 180 oz.; metabisulphite, $\frac{1}{2}$ oz. I cut this down to 1 oz., and as soon as the bath discolours it is discarded, with the full knowledge that its fixing powers, although still efficient, are approaching the danger line. Similar experiments can easily be made by anyone, and proportions decided to suit individual requirements.

To my mind this furnishes a surer test of the number of prints that a bath may be used for than the plan suggested by Mr. Stine, whose contribution to the "Photo Era" has been so ably dealt with by yourselves.—Yours faithfully,

Pontypridd.

ALBERT O. FORREST.

THE ASSISTANT QUESTION.

To the Editors.

Gentlemen,—The future of photography, the relation of employers to assistants and the training of the latter are questions that are intimately related to each other. No doubt economic forces not altogether under our control will be the predominant factors in determining future developments, but unless we are to sit down with folded hands and say, "Kismet," we may as well bring what intelligence we have to bear on these questions. So far as portrait and general work is concerned it may, I think, be conceded that an all-round experience such as would be got in a personally-conducted business employing from three or four up to a dozen persons in a good middle-class neighbourhood, affords the best opportunity at starting for securing that general practice in varying kinds of work which every youthful photographer should, if possible, obtain before specialising.

There are, however, not enough of these berths to go round, and in any case there is the fact that a considerable number of youths drift into the photographic business with only a partial training. One has only to look through the trade advertisements of the "B.J." since demobilisation got in full swing to see what a considerable amount of work is being catered for by trade workers in the way of printing and enlarging, and to realise what a restricted experience the younger workers engaged in postcard and similar machine printing are likely to get. Also, it will be noticed that in London technical work is being organised on limited company lines, where formerly it was undertaken by individual workers on their own account or in partnership with another operator. There is therefore a need that technical workers, printers and enlargers should organise themselves almost more than for portrait operators. Doubtless in a year or two, as Mr. Fisher's Act comes into operation, some of the younger workers will have to attend classes in the day-time, but meanwhile a good number will have passed the age limit at which attendance is compulsory. On the portrait side, what I should like to see, and what, if the war had not broken out, I was hoping might be discussed informally at a conference of the P.P.A., is the practicability of a number of P.P.'s engaged in somewhat similar work but with businesses of different sizes getting sufficiently in touch with each other to be able to pass on their junior assistants from the smaller to the larger concerns, where more experience could be gained, instead of all engagements being left to advertising.

The Edinburgh P.P.'s are to be congratulated on having started their retouching class, and those in other large towns ought to follow the example. The teaching, however, should be confined to those definitely engaged in a photographic business, otherwise we may easily get a much larger supply of retouchers than we need. Retouchers do not wear out in twelve months, like a suit of clothes.

I hope we shall hear more of Mr. Adams's scheme for instruction by postal lessons.—Yours, etc.,

LOOK FORWARD.

FORTHCOMING EXHIBITIONS.

April 17 to May 22.—Hammersmith Hampshire House Photographers' Society Annual Exhibition. Two open classes. Joint secretaries, J. G. Abrahams, 41, Hamilton Terrace, London, N.W.8; A. H. Page, 12, Lame Grove, London, W.12.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

G. H.—There is no doubt that the stains are due to particles of rust on the paper. The best remedy is to filter the tap water through a bag of flannel, which probably is more easily attached than one of the filters sold for ordinary water taps.

H. J. C.—There is no reason why the developer made up according to your formula with pure chemicals should go black. We can only suggest that some of your chemicals are of bad quality, or there has been contamination from the dishes or bottles.

E. J.—We think you should be able to do fairly good work in the lean to you describe. It is rather short for full-lengths, but for heads and half-lengths it is quite practicable. It will be desirable to have white curtains to cover all the glass when the sun is on. You will hardly require dark blinds, as you have not a great area of glass. The specimen you enclose is rather flat. Perhaps you overdo the reflection.

E. V. M.—The lens appears to be a rapid rectilinear. The apertures as marked cannot be f /values, as the fullest possible aperture is only about f /8. It is rather difficult to unscrew cells once they are tightly fixed. An optician would turn up a boxwood chuck and tap the lens into it. We have found the best way is to fit the cell into a Thornton-Pickard shutter with the rubber moulding very tight. This will generally give enough purchase to turn it.

L. L.—Box top negatives are purchased by firms who specialise in these for people making the chocolate boxes for the well-known firms. They are Messrs. Lilywhite, Ltd., Dunkirk Mills, Halifax; the Rotary Photographic Company, West Drayton, Middlesex; and Philip G. Hunt, 332, Balham High Road, London, S.W. Usually the negatives are bought in sets of six, and an average price is a guinea per negative, although more is sometimes paid for exceptional subjects.

T. F. C.—(1) We should say that exposures of rapid bromide paper from average negatives would not be more than a second or so with the 100 c.p. lamp: approximately double this time with the 50 c.p. lamp. The arrangement seems to us excellent. It is, in fact, that commonly adopted for box printing machines working from an incandescent mantle. (2) There are no books worth mentioning on professional photography, but we have a little manual, "The Portrait Studio," from which no doubt you could gain some help, issued by our own publishers, price 10d. post free. (3) Half-plate negatives are altogether too small for glazing the studio. You would be pretty certain to have a lot of trouble from leakage in bad weather, and our own opinion is that it would be false economy to avoid the cost of glass of the ordinary larger size.

O. E.—1. There have been no formulae published so far as we know of Monomet-hydroquinone for tank development. Certainly no time and temperature tables for this developer are available. Very likely you could obtain these data from the White Band Manufacturing Company, Progress Works, South Croydon, but, failing that, it should not be difficult to adapt the ordinary Monomet-hydroquinone formula to tank development, say, by

adding some more sulphite and by finding the degree of dilution which will give you a sufficiently strong negative in from fifteen to twenty minutes. 2. We do not know a twin-lens N. and G. reflex, and we rather gather from the other data that you give that you refer to the ordinary single-lens reflex. If this is so, a fair price to a direct purchaser would be about £25. A dealer would give you only about £15.

F. A.—No assignment of copyright or licence to issue copies of a copyright work such as that of the "Wreck" is valid in law unless it is in writing signed by the owner of the original in respect of which the assignment or licence is made. The permission which you have received has been of a very irregular kind, and we think it would be difficult for you to prove through your witnesses that you had made to you definitely a partial assignment of the copyright, for example, to issue postcards. The letter merely asks you not to print any more cards. Evidently there can be no objection to your disposing of those which you have left, and we cannot see that you will be harmed by making the acknowledgment of the authorship of the enlargement. In these copyright matters to be forewarned is to be forearmed, and we would direct your attention to the little manual, "Photographic Copyright," issued by our publishers.

H. II. T.—Even with your 29-ft. run the longest focus lens you can use for full-length C.D.V.'s is 8½-in. focus, which is too short for the best result from half-length cabinets, and still more from cabinet heads. We advise you to give up trying to do all the classes of work with the one lens, and to choose a focal length which will enable you to take half-length C.D.V.'s within your 29 ft. and at the same time is long enough to give you satisfactory results in portraits taken at closer quarters. For this, the focal length need not be more than 13 ins., and generally speaking you would not find any ill effects from working with the Dallmeyer 3 B of 11 ins. focus. We advise the choice of either this lens or the Ross Portrait No. 3 of 12 ins. focus, or one of the Cooke portrait lenses of about 12 ins. focus. Either of these is preferable for pure portraiture to an anastigmat, although, of course, the latter has its use in making large groups of whole-plate, or even, at a pinch, 12 x 10.

H. F.—1. Without seeing the print we should say that the only means of making a satisfactory copy by the use of filters is by using a red filter such as the Wratten 29F, with a panchromatic plate. But as we imagine it would not pay you to get a filter for this special purpose you might perhaps put out the making of a copy negative to a firm such as Mr. Stewart Bale, 53, Lord Street, Liverpool, a specialist in orthochromatic work. Otherwise you might try what benefit you could get by photographing with the deepest yellow filter you have and a panchromatic plate, though we should doubt if the advantage would be very great. In most cases such as this the most practical method is to make the best negative you can by ordinary means, from that an enlargement, work up the latter, and from that make a new copy negative. 2. If the work is of good quality we should say at present time from £1 to 30s. for each negative and one print supplied therefrom.

P. L.—(1) With the Dallmeyer and Cooke lenses you can obtain absolutely sharp portraits, but also, by adjusting the lens, you can obtain a certain moderate degree of diffusion. Many professional photographers think this diffusion is quite enough, but, on the other hand, many amateurs go in for much more diffusion than these lenses will give, and for them there are the "Verito" and the "Portland." The former is made by the Wollensak Optical Company, and sold in this country by Messrs. W. Butcher and Sons, Camera House, Farringdon Avenue, E.C.4. The latter is sold by Messrs. Sinclair, 54, Haymarket, S.W. (2) There is no exact focal length for a plate of a given size. It is a question of choosing the lens of longest focal length which you can use in a given space or which can be fixed to the camera. A 10-in. lens (25.5 cm.) of the portrait type would not cover your 24 x 18 cm. plate well enough, although an anastigmat would. We think your best course would be to state the exact size of the lens panel of your camera to the maker of the lens which you think of having, and thus to find out if the camera will carry it.

K. T. IDA.—(1) It is certainly true that plates of moderate speed such as H. and D. 250 are used when circumstances so require for very rapid focal-plane exposures at an aperture of say, $f/6.3$, and that a good deal can be done by humouring the plate in development, especially by using the developer warmed to a temperature of about 70 to 75 deg. F. But we think $f/16$ is altogether too small a stop for such rapid exposures except in very brilliant light and with open subjects such as seascapes or sailing boats. Probably Dr. Abrahams had these in mind. Generally speaking, the practice among users of focal-plane cameras is to employ the fastest plates obtainable and to develop in the ordinary way. (2) The gamma infinity of a plate is a property which permits of more satisfactory results being obtained at very short exposures than those from a plate exposed under the same conditions, which has merely a much higher speed number. Thus, for the purpose of very brief exposures this property of the plate is a very important one, although the matter is largely ignored by users of focal-plane cameras. The only book by Dr. Mees is "Investigations on the Photographic Processes," published by Messrs. Longmans, price 6s. 6d., which you could obtain from a Japan firm.

R. G.—(1) The 2,000 c.p. is much too small a light for short exposures, and, indeed, for the best kind of lighting. We advise you to get a copy of the "B.J." of October 26, 1917, price 4½d., from our publishers, and have your electricians install the lamps on one or other of the systems there described. We should say 4,000 c.p. is a minimum for full-lengths and small groups. An important point, too, if you do any photographing of children, is that the lamps should be made to lower. (2) The address of the licence office, now administered by the Ministry of Labour, which applies to your district is: The Secretary, New Business Licences, New Arts Buildings, Liverpool. A form of application can be obtained at your local Employment Exchange. (3) Depending on the class of work, we think the camera should not be larger than whole-plate, and perhaps half-plate would do. You should have one with a repeating back or with one of the special backs allowing of a number of small portraits to be taken on a single plate, and postcards, etc., made by enlargement. This is very largely done now both by cheap and better businesses. For full-length cabinets and postcards a good length of focus is 11 ins., such as has the Dallmeyer 3 B. At any rate, if you do not want to pay the price of this lens (cheaper second-hand) we should advise either a less reputed portrait lens or an anastigmat of about the same focus. But for artificial light work the aperture should not be less than $f/4$.

SUMMARY.

The eleventh Colonial and Foreign Number of the "British Journal" will be issued on June 6 next.

Given a sufficient response, a special section in this issue will be allotted in the announcements of situations wanted to those advertisers wishing to seek employment abroad. (P. 239.)

In his article this week "Practicus" deals with further matters connected with the use of portrait lenses in the studio, and has advice to give on the selection of focal length in relation to the character of the work and the size of the studio. (P. 232.)

A writer in "American Photography" has published his ideas of the features which he regards as essential in a camera of the vest-pocket type. These are: A construction which protects the lens without the need of a case, automatic spring into the position of focus, and focussing adjustment. (P. 234.)

In a leading article we deal with some of the somewhat indefinite transactions which, in the absence of recognition beforehand of their nature, may give rise to disputes. A frequent instance is the photography of club groups, whilst others relate to photographs unpaid for and to negatives taken but not used in executing a sitter's order. (P. 230.)

A contributed article deals with methods of dissection of the costs in the production of photo-engraved blocks. (P. 231.)

Working details of the methods for the repair of broken negatives are contained in a contribution to "Assistants' Notes." (P. 235.)

In working out a metabisulphite-hypo formula for a fixing bath which will begin to stain just about the time that it ceases to fix efficiently, use can be made of the strip of unexposed dry-plate as a test of the latter condition. (P. 229.)

Changing boxes, living-portrait photographs, and a camera attachment for aerial photography are among the patents of the week. (P. 236.)

Official details just published mark the enormous development of the Photographic Section of the Air Force. Only forty negatives were taken during the first month of the section's existence, whilst in October 1918, 23,000 negatives were exposed and 650,000 prints issued. (P. 238.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

Further details are given of the process and apparatus of Mr. Aron Hamburger for the production of complete colour cinematograph films. A colour impression is applied simultaneously to each side of the film band. (P. 17.)

The report of the lecture by Mr. S. H. Williams before the Royal Photographic Society very clearly shows the steps by which a banded colour filter such as that employed in the Joly process can be made by comparatively simple operations and apparatus. (P. 18.)

The current instalment of the "Decennia Practica" of colour photography contains further details of the Cheron process of photography in colours by prismatic dispersion. (P. 20.)

EX CATHEDRA.

The B.J. Colonial Issue.

The eleventh Colonial and Foreign Number of the "British Journal" will be issued on June 6 next. Its special feature, which now, so we may believe, is fairly familiar to the photographic trade, is that it is printed in an extra edition identical with that circulating in the ordinary course, but which is posted directly to the number of 5,000 copies to photographers, photographic dealers, photo-engravers, and others throughout the British Empire abroad and in foreign non enemy countries. The business-bringing power of the issues previously distributed on these lines is now an oft-told tale—a tale told to us again and again by advertisers who have repeatedly proved its truth. It is not too much to say that this one "B.J. Special" of the year is unique among issues of photographic periodicals in the volume of advertising it has carried and in the regularity with which the announcements of photographic dealing and manufacturing firms, large and small, have appeared in its pages. The proof of the pudding is in the eating, and firms in this country have learnt for themselves that a single announcement in this issue has brought them not merely many times the amount of their expenditure on it, but substantial additions to their circle of regular customers. With the release of industry from wartime restrictions it may be expected that the opportunity of addressing buyers of photographic goods whose wants have been scantily filled during the war will be embraced upon an exceptionally large scale.

Situations Abroad.

It has been suggested to us by several photographic assistants that in the forthcoming Colonial and Foreign Number we should make a special section for the announcement of assistants who are seeking situations and are ready to go abroad. It may readily be believed that the experiences in different parts of the world which have been the lot of many assistants through their service in the Army have provided an inducement to many, who previously were confirmed stay-at-homes, to seek occupation abroad. In one or two of the early Colonial Numbers we introduced a section for announcements of this kind, of which a fair number appeared. In the present national conditions it is very possible that a much larger number of assistants are likely to announce their willingness to take posts in the Colonies or in other parts of the world. At any rate, if the number of applications of this kind is substantial we will certainly gather them in a special section, the title of which shall make it clear to the photographers into whose hands the issue comes that they are announcements by advertisers who are seeking jobs abroad. Assistants need not, therefore, go to the expense of stating this fact in their announcements, although they may advisedly mention the country for which

they have a preference. In any event they should state when sending the advertisement that it is intended to appear in any section of this kind which may prove of sufficient size to form a feature of the issue. The sooner such applications are sent in the better. On the general question a word or two may be said. It would be an ungenerous want of candour to lead any assistant to suppose that if he has not been successful hitherto in this country he will nevertheless be satisfactory to an employer in Auckland or Buenos Aires. Broadly speaking, the demand for quality of work and general efficiency is as insistent in the larger colonial and foreign towns as it is here. In Melbourne, for example, at any rate before the war, competition among photographic studios was even sharper than here. So that an assistant, so far as his employment is concerned, needs to guard himself from falling into the error that on the other side of the world he is going to have an easy time or to satisfy people, though he has not been able to satisfy employers here.

* * *

A Fixing Bath for Prints.

The suggestion made by Mr. Albert O. Forrest in a letter last week is one which deserves to be kept in mind, since it is certainly one which should contribute to security in the systematic fixation of development prints. It will be remembered that Mr. Forrest advocates cutting down the metabisulphite in an acid fixing bath, containing only this addition to the hypo, with the object of causing the bath to give rise to stain by the time that its fixing properties are exhausted. It can be easily understood that the ratio of metabisulphite to hypo, namely, 1:18, which Mr. Forrest suggests is one which may vary with every individual set of circumstances. The degree of freedom of the developer from staining tendency will obviously modify it, as will also the photographer's practice of rinsing or omitting to rinse prints between development and fixing. But the suggestion is, as we have said, worthy of notice on account of the fact that it removes what is a real practical objection to a fixing bath which keeps free from stain as long as it is used. The hypo-metabisulphite formula is as good as any for the making of an acid fixing bath, and its modification on these lines is a measure both of economy and efficiency. The requisite quantity of metabisulphite could readily be ascertained by a few tests, using the strips of dry-plate which we have so often recommended as a rough-and-ready but sufficiently reliable test of the degree of exhaustion of a print-fixing bath.

* * *

Army Photography.

From a White Paper recently issued by the Air Ministry we learn that photographic reconnaissance in 1914 was confined to two officers and three other ranks, whose outfit consisted of two cameras and a portable box of developing chemicals, while by the end of 1918 the personnel had increased to 250 officers and 3,000 other ranks. The increase in equipment and materials to the same date is not stated, but is probably quite proportionate. There must be a vast stock of apparatus and materials which on the final cessation of hostilities will not be required, and we trust that it will be made available for civilian use before it has hopelessly deteriorated. There has necessarily been much waste through imperfect storage during the war, but much of the material should be in good condition. As regards apparatus, the special cameras used will not be of much value to outsiders, but dealers and photographers would be glad to get hold of some of the lenses to tide over until our optical factories are in full swing again. There is another question to be considered—the disposal of the 3,000 more or less trained men. Many were photographers before the war, but a very large number will

doubtless desire to take up photography in civil life. The openings in this direction have been greatly reduced by the large influx of women as operators, printers, and retouchers, and in the absence of any organisation there is grave danger of wages sinking to the pre-war level, a prospect which is not pleasing. The remedy would seem to be for the employers to insist on some standard of proficiency, and to pay a rate of wages commensurate with that ruling for skilled workers in other trades.

SOME BUSINESS PITFALLS.

THE legal rights and liabilities particularly appertaining to their business may be said generally to be well understood by photographers. It is rare now to find ignorance of the facts as to ownership of the negative or of the sitter's rights in the non-display of his or her portrait. Even if a photographer may not be familiar with one express description of infringement as exhibition "by way of trade" contained in the Copyright Act, he knows it as a matter of fact, and is careful to ignore it only in those cases where he realises that objection is not likely to be raised by the sitter. But such considerations as these may be said to be the ABC of the law involved in the making and reproduction as exhibition of photographs which are taken in the ordinary course of business. There are others which are by no means so clearly or widely understood, partly from the fact that they are not so definite in character themselves, and partly that they are of less frequent occurrence. One or two of these, therefore, may well be the subject of a few notes, a glance at which will serve to tell the photographer what his course should be when the occasion arises.

Perhaps one of the most unsatisfactory problems which can arise, if the conditions involved in it are not recognised before hand, is in connection with the photography of groups and similar subjects. A typical case may be said to be somewhat on the following lines:—A photographer is asked to take photographs of, say, a cricket team. The order is that he should supply copies of the group to the team, and that therefore he should quote a price for the prints. Now, very often when the group comes to be arranged, it occurs to the photographer that a subject such as this is one which he could make use of in his own business in the way of selling prints or issuing postcards, and therefore it occurs to him to ask permission to make an exposure "for himself." No doubt whatever that when he makes this request he understands that the right to reproduce such photographs will belong to him and to nobody else. At the same time it is very likely not at all clear to the officers of the cricket club that in giving this permission they have conferred these rights upon the photographer. So at the start there is the material for misunderstanding. On the prints being made it is only natural that the photographer should submit proof from the negative taken "for himself." There is no reason why he should not, because obviously he has the right to supply prints if he so wishes. And the club most probably will not worry itself to draw any distinction between this photograph and those which it ordered, even if—which usually is not the case—it has the means of distinguishing the one from the other. Thus, the club may be supplied with finished prints of the photograph in which the photographer has, as he knows, the rights of reproduction. It is at this stage that the trouble usually begins. A common source of it is that the club, finding that large photographs are somewhat expensive, may send away a large print (the photographer's copyright) to somebody else to be copied and issued in, say, postcard form.

The club will think that as they paid for the prints they have a right to have them copied. The photographer, on the other hand, thinks quite the contrary, and when he finds that copies have been made he hastens to make a claim upon the club in respect to damages which he considers he has sustained. In such cases the question at issue is: Has he or the club the sole right to copy the photograph?

Now a dispute of this kind is very liable to be altogether unprofitable, from the fact that the evidence will be verbal evidence, and as likely as not, if the case were heard by a county court judge, the evidence of one side would be largely contradictory of that on the other. In the first place there is the uncertainty of identifying the photograph which the photographer, as he alleged, was allowed to take "for himself." And even if that could be identified, there is still an element of doubt, for the club may quite properly argue—and they could find considerable legal support for such an argument—that when they gave the permission it was with a view of the photographer supplying them with copies, not that he should publish copies broadcast. The photographer, on the other hand, will represent that certain photographs were taken by him to the order of the club, and that the club were liable for payment of the prints from them, whereas in the case of the special one "for himself" there was no such liability on the part of the club. It should be pretty evident that in circumstances such as these, where evidence may be flatly contradictory, and where also we are considering some of the most delicate refinements of copyright law, it is in the highest degree doubtful in whose favour a judgment is likely to be given. The moral of such a tale is that if a photographer is anxious to obtain copyright in one such special exposure he should obtain the written permission of the club for the work to be done, such statement briefly identifying the photograph, say, by the position of one member of the group, and also acknowledging the photographer to have the sole right of reproduction. If the confusions and uncertainties to which such transactions as this may easily give rise are recognised in advance, it is quite easy to draw up a simple statement which will remove altogether any possibility of subsequent dispute.

Arising out of such work as this—of photographing groups by appointment—are the annoying incidents which sometimes arise from some other photographer—very often a pressman with a hand camera—turning up while the group is being arranged and making a negative for himself. Perhaps this poaching upon the preserves of the appointed photographer is a less common thing than it was some years ago. However, it appears even on another page of this issue, where a correspondent points out that a news-

paper journal calmly suggests that the pressman and the photographer who has been commissioned to take the group should carry out their work together—in other words, that the poacher and the gamekeeper should fraternise. There is, unfortunately, no remedy against men who are so deficient in the sporting instinct as to take advantage of the opportunity which another man has secured. Let the appointment photographer be under no illusion: there is no copyright, and can be no copyright, in the arrangement which he may give to a group of persons. In copyright law such a subject is a "work of nature," and it is not possible to obtain a remedy against a man who thus despicably profits by the skill of another. Competition of this kind, in the experience of many photographers, has yielded some amusing incidents, since the only effective preventive of such practice is to get someone continuously to obstruct the view of the interloper's camera until the legitimate photographs can be made and the group dispersed.

In conclusion, a word or two may be said on conditions which constantly arise in the ordinary course of business of a photographic studio. Sometimes it may happen that a sitter does not pay for the photographs which have been made, and thus a photographer, failing to obtain payment without recourse to legal means, may think to himself that, as he has not been paid for making the pictures, the copyright in them belongs to him. Such is a complete error. As can be seen in a moment by anyone who has realised that the beneficent laws of England are made for the profit of lawyers, the real law of the matter is that if the sitter does not pay he or she can be sued for the money by the customary legal methods, but at the same time the sole right to reproduce or exhibit the photograph belongs to the sitter. In law, we believe, no distinction would be drawn between a sitter who does not pay because he or she thinks that the photographs are unsatisfactory and one who accepts the prints and endeavours to evade payment. Somewhat closely related to the same minor problem is the case of the surplus negative—that is to say, the negative or negatives which are made at a sitting, but which are not used in carrying out the sitter's order from one reason or another. The question is referred to because there have been cases in which the photographer has claimed the rights of reproduction in such negatives. Legal judgments have, however, firmly established the contrary, on the ground that the payment made for the supply of the prints was a consideration for the whole labour of the artist, and that therefore such payment covered both the photographs which were approved by the sitter and the others which were not.

COSTS IN PHOTO-ENGRAVING.

It may be useful to outline a cost system which gives the facts, as operated in a small establishment in America having seven men (including artist) on the shop pay-roll.

When a job comes in a duplicate numbered job ticket is made out; one goes with the copy and the other remains in the office.

Every workman has a daily time card. When he starts in the morning he stamps his card in a Baird time clock and picks up his job. As soon as he has finished his part and passes this job on he stamps his card in the time clock and writes the number of the job in the space between the two lines, which thus mark the time he commenced and the time he finished, and this shows the time in hours and tenths he

has spent on that particular job. The same with every job he tackles during the day. If he is not working on any numbered job, but doing something else, such as making-up chemicals, he marks the card "Miscellaneous." This card, therefore, shows the chargeable hours shown by the job numbers, and the time without job numbers is non-chargeable time.

The next morning the stenographer collects the time cards, and transfers the time shown on the time cards to the various job ticket duplicates, according to the number of the job. So that at any moment it can be seen how much time has been spent upon any particular job up to the night before. The "Miscellaneous" or non-chargeable time is entered up on a separate sheet under each man's name. When the engraving

is completed it is brought into the office and measured up, and the square inches also noted on the job ticket, in order to calculate the material used per square inch sold.

The material used is arrived at by careful stocktaking on the first of every month. The stock in hand at the first of last month, plus the amount purchased during the month, less the amount left at the first of current month, shows the amount consumed during the previous month. This value divided by the number of square inches sold gives you the value of material per square inch. It varies from month to month from 2 cents (1d.) to 4 cents (2d.), but it averages up over a year to nearly 4 cents (2d.).

Having the productive labour on every particular job and the material cost, we have now to add our overhead or burden, which consists of all other expenses—the non-chargeable time, supervision, office charges, rent, rates and taxes, insurance, advertising and selling expenses, depreciation of machinery, interest on investment, and, in fact, every other expense.

These three items—labour, materials, and overhead—added together give you the cost, and the difference between this total and the selling price gives the profit or loss on any particular job.

Now, there has been a great deal of discussion concerning the method of apportionment of the overhead on each particular job, and, on the whole, it would seem to be simplest in a small establishment to add all the overhead items together and divide by the number of chargeable hours, and add the sum found to each chargeable hour. Thus a month having 1,000 chargeable hours and total overhead expense of \$750 equals 75 cents per chargeable hour, and if any particular job has ten hours' labour on it, \$7.50 cents, is added for overhead to the cost of labour and materials to make up the total cost. This, of course, is not ideally fair, but it is fairer than charging a percentage on the labour cost, because thus the overhead on the cheaper man is less than the overhead on the expensive man, whereas both require the same space, and frequently the cheaper man requires more supervision. On the other hand, it ignores the extra overhead the job needing the use of machinery ought to pay, and this is spread over all the chargeable time; but as 10 per cent. per annum depreciation cost of machinery is not

very considerable, and some of the machinery is used on nearly every engraving, it is scarcely worth while to separate this item. The overhead varies every month according to the number of chargeable hours worked, ranging from 68 cents (2s. 10d.) in the busiest time to \$1.30 (5s. 5d.) in the slackest month. It averaged the first half of last year 75 cents (3s. 2d.), and we used that figure for the next half-year; the figures ascertained by the half-year's costing will be used for next half-year.

The inventory, if taken carefully, will show exactly what waste has taken place. For example, on the average 35 per cent. more metal was purchased than the square inches sold, and some months this has gone up as much as 45 per cent., and has never gone down lower than 25 per cent. It shows the cost of metal is one-third the cost of all materials; it will also show fluctuations in the consumption of any materials. For example, silver nitrate: the average monthly consumption of this chemical is \$7.74 (£1 12s. 4d.), but it varies from \$4.34 (18s.) to \$14.50 (£3 0s. 5d.). When a high consumption like the last is shown, naturally, some explanation will be called for.

The usual way of summarising the cost in the photo engraving is to take the shop pay-roll (calling it labour), then materials, and then overhead, which includes all the other expenses. As has often been shown, the rough average from many establishments on this basis is: labour, 50 per cent.; materials, 15 per cent.; overhead, 35 per cent.; and our figures were very close to this average at first, but last year the percentages worked out rather differently; they were: labour, 47 per cent.; materials, 11 per cent.; and overhead, 42 per cent. This is due to the fact that a good many duplicates have to be made and the negatives are stripped on to Kodaloid and saved and used over, so that the labour, time, and the material used in making the negative is saved, whereas the establishment expenses remain the same; therefore overhead goes up in relation to the cost of material and labour. Overhead is really a much higher percentage than is shown on this scheme, because the non-chargeable hours part of the shop pay-roll which is overhead is included in labour, instead of overhead, and it is never less than 15 per cent. of the pay-roll.

A. J. N.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
The Camera and the Lens (Jan. 10).
Managing the Sitter (Jan. 17).
Backgrounds (Jan. 24).
Studio Exposures (Jan. 31).
Artificial Lighting (Feb. 7).
Printing Processes for Portraiture (Feb. 14).
Studio Accessories and Furniture (Feb. 21).
The Surroundings of the Studio (Feb. 28).

Studio Heating and Ventilation (March 7).

MORE ABOUT LENSES.

ALTHOUGH the lens is the most important and usually the most costly item in his outfit, the average portraitist has very hazy ideas as to its powers and qualities. If he is a cautious man and plays for safety, he is usually satisfied with getting lenses similar to those which he knows have been used successfully by others; while if he has more enterprise and cash than he has experience he will procure the latest thing in anastigmats, which may or may not be the most suitable for his work.

In choosing a lens for professional portraiture there are three vital points to be considered: focal length, working aperture, and quality of definition. I will deal with these seriatim.

It cannot be too often repeated that the perspective or "drawing" of a picture depends upon the distance between the eye of the artist, or, in the case of a photograph, the lens of the camera, and the model. If this distance be short

the perspective will be abrupt, while if it be too great there will not be sufficient convergence of the lines to give an impression of solidity. The first condition exists frequently, the second rarely. This leads us to our first point, the selection of a lens of suitable focal length. For this we must first decide the minimum allowable distance between lens and sitter when making the largest head which is likely to be required, and this is generally put at 6 ft. To find the focal length the first thing to be done is to divide the actual size of the sitter's head, which we will say is 9 ins., by the size it is to appear in the negative, say 3 ins. This is a reduction to one-third, and according to the well-known rule for this we must place the lens at four times its focal length from the subject. But as we have already fixed the distance as 6 ft., we must divide that by four to obtain the equivalent focal length of our lens, and this, of course, is 18 ins. I have given these measurements as an example, but as a matter of practice 18 ins. is a very useful focal length for general work, provided that the studio is of average length. In a short studio it would be impossible to make full-length cabinets with it, and it would be close work even for half-lengths. In many studios a 16-inch lens is preferred, and will answer very well if not pushed too far with large heads. Unfortunately, it is difficult to judge the amount of what we must call distortion by looking at a print. The photographer himself cannot see it in the absence of the sitter, but the sitter's friends can see it and condemn the likeness, although they are unaware of the cause. This is, I believe, one of the reasons why small portraits are usually more acceptable, and often have to be enlarged, although larger direct negatives are available. A little experiment which will be instructive to the photographer who has no knowledge of the theory of perspective can easily be made. Instead of a sitter's head place a cubical wooden block or cardboard box with 9-inch sides, and photograph it with a 9-inch lens, one angle being turned to the camera, so that a 3-inch image is obtained. Then repeat the operation with an 18-inch lens and compare the results. The difference is striking, and although not so immediately apparent, exists to the same extent in two portraits taken under the like conditions. Of course, a portrait lens is not necessary for the experiment; a $8\frac{1}{2}$ or 9-inch R.R. will answer, using the complete lens for one exposure and one of the components, either front or back, for the other. Those who have access to T. R. Dallmeyer's "Telephotography" will find an excellent pair of examples, the subject being a half-length portrait, taken with a 16-inch lens and a telephoto lens respectively. My advice is not to try to do everything with one lens, but to use an 18-inch for all work within its scope and to procure one of shorter focal length, say 10 or 12 ins., for small full-lengths.

I now come to working aperture, another important factor, especially as regards cost. Almost from the inception of photography opticians have turned out big lenses with big apertures, because photographers asked for them and were willing to pay high prices. Practically, I do not think that a larger aperture than $f/5.6$ is needed for lenses of 18 ins. or more, as the lack of depth that is present at larger openings is sufficient to spoil any portrait, especially if taken at close quarters, when rapidity would be most needed. With smaller lenses much larger apertures are allowable, as these are often required for small portraits of children, where the distance from the subject and the shorter focal length aid in giving depth when speed is the all-important consideration. Thus I consider such lenses as the Dallmeyer 3B and the various $f/3.5$ 12-inch anastigmats of other makers as invaluable auxiliaries to a larger lens. Do not think that depth of focus is in any way affected by lens design. It is absolutely a matter of relative focal length and aperture, and a poorly made lens often gives

greater apparent depth than a good one, but of this I will say more later on.

One has only to look at any representative collection of modern portraits to see that there is now no rigid standard of definition as there was a few years ago. The ordinary person is getting educated into the appreciation of soft definition, and pictures which formerly would have been rejected are now accepted as orthodox. Of course, the standard of definition will vary with the class of clientele, and I would certainly not advise the postcard artist to invest in a Portland or Puligny-Puyo any more than I should suggest that a short-focus portrait lens was the correct thing for Bond Street. However, the general tendency is in favour of less critical sharpness than we saw formerly, and this is all to the good, for it minimises retouching and gives a better chance to the general effect of light and shade.

There is now available so great a variety of lenses, rapid enough for portraiture, that it is rather bewildering to the novice. First we have the portrait lenses of the Petzval and Dallmeyer types, with which nearly all professionals are familiar. These give intensely sharp definition over a comparatively small area, the marginal definition being spoiled by curvature of field and astigmatism. The former defect may be cured by reducing the aperture, but the latter cannot. I may say that for some subjects a lens with a curved field scores over all others. For example, a three-quarter length sitting figure can be better rendered with a curved field lens which is practically free from astigmatism than by the best modern lens and the swing back. Fortunately curvature of field and astigmatism are seldom, if ever, present in an aggravated form in the same lens. If it be desired to choose between two lenses it is easy to tell which has a round field and which has astigmatism by focussing a small flame, or even a disc of white paper on a black background. If astigmatism be present, it is impossible to secure a sharp image on the margin of the plate, no matter how much the screen is moved. The image of the flame or paper disc will be distorted one way or the other as the screen is moved to and fro, and at the neutral point it is unsharp. With a round-field lens it is easy to obtain sharpness at the margin, but at the expense of central definition. With sitting figures this is just what is wanted, as the nearer parts of the subject fall on the margins of the plate, and the head near the centre. When a similar subject is taken with a good anastigmat it is possible to get the head and knees sharp by using the swing back, but the body will be out of focus if a large aperture be used.

We now come to the question of spherical aberration as affecting definition. If we attempt to focus a very finely engraved line subject or a page of very small but sharp type, and find that we cannot obtain critically sharp definition at the full aperture of the lens, it may generally be assumed that spherical aberration is present. If in large quantity a halo will be visible around larger type, or, in the case of a male sitter, round the white collar. This is clearly seen with the Portland and Berghelm lenses. It usually disappears on reducing the aperture to $f/16$. Now, properly used, spherical aberration is a very good thing, and many portrait lenses are now made so that any desired quantity can be introduced. This is effected by altering the distance between two of the component glasses, and to do this we turn the back cell in the Dallmeyer model and the front one in the Cooke. We can by this simple adjustment obtain any degree of diffusion, from nearly sharp to quite fuzzy. For professional work I am in favour of lenses of this description rather than those made specially for soft focus work, as the latter are more limited in their application, and cannot be used for sharp pictures requiring short exposures.

Child portraiture, while one of the most remunerative

branches of our work, is also one of the most difficult, and it is well to be provided with a very rapid short-focus lens, which can be used in a poor light or with very restless youngsters. I have found it well worth while to keep a special "baby camera" always ready for use. This is of the ordinary studio type fitted with a 9-inch portrait lens working at $f/3$, and one of Dallmeyer's rapid cabinet attachments. This combination makes work very easy, as it is possible to work fairly close up and yet get fairly good depth. Only full-lengths or fairly small heads should be attempted, as these can easily be enlarged. I can recommend this course, as I have thus saved hundreds of re-sittings which would have been necessary by attempting to work in the ordinary way,

besides getting a reputation for being "clever with children."

In recapitulation, I suggest as a serviceable outfit for work up to whole-plate size and for 12 x 10 full lengths, an 18-inch lens with an aperture of $f/6$ and a soft focus adjustment for the bulk of the work, an 11 or 12-inch lens working at $f/4$ for full-length cabinets and C.D.V., and, if possible, an extra-rapid 9-inch lens for young children. Any or all of these may be anastigmats, as these may, if necessary, be used for ordinary outdoor work as well as for portraits. Portrait lenses of the ordinary type are not so available, as nearly all of them will give a flare spot when used with a small aperture in bright light.

PRACTICUS.

SPECIFICATIONS FOR A VEST-POCKET CAMERA.

[The study of the features desirable in the vest-pocket camera, which we quote from our contemporary, "American Photography," is one which must have been written without a full knowledge of what English makers have done. The three features which Mr. Morse declares to be unrealised in any single camera are, we think, embodied in at least one camera here; if not in the precise form which Mr. Morse specifies, at any rate in one which is its practical equivalent.—Eds. B.J.]

In a passage that becomes more and more significant as time goes on, Alfred Watkins, the English photographic expert, speaks of his preference for a whole-plate camera, but is willing to concede that a 5 x 7 camera might possibly be used in its place, if one seriously objected to the weight of a larger camera.

Since those days, much water has flowed beneath the photographic bridge, and few people ever think now of packing about a 5 x 7 camera, except for some specific and unusual occasion. In fact the tendency is distinctly towards a rather small camera, a movement that was perhaps inaugurated in Great Britain by the Shew XIT and the Houghton Ensignette cameras. Some ten or a dozen years ago I wrote to some American camera manufacturers suggesting smaller cameras; they replied that there was no market for such a camera. To-day the woods are full of them.

The amateur photographic public is evidently getting educated to the possibilities of the small camera. Possibly the economy enforced by the war was largely responsible. At any rate, the so-called vest-pocket camera is having a large and increasing sale. The American film camera has now reached a stage of excellence such that further considerable improvements seem unlikely. The vest-pocket camera, however, has several points that need improvement, and I propose to point out some deficiencies in those now on the market.

First let us consider what the V.P. is used for, where, when and how. The size of picture is about $1\frac{1}{2} \times 2\frac{1}{2}$ inches. The camera is about $1 \times 2\frac{1}{2} \times 5$ inches. Its weight is from eight to ten ounces. It easily fits into the upper vest pocket of a man's clothes, opposite the heart or on the other side, provided the usual size pocket is enlarged to fit the camera. On a hot summer's day it probably had better not be carried so close to the body.

The V.P. is pre-eminently a snapshot camera for the expert worker. In fact the smaller the camera, the greater the skill of the operator must be to obtain good results. It is a camera particularly adapted for genre work—pictures that show up suddenly and disappear again; a policeman holding up an impressive hand while a dainty little miss crosses the avenue through a lane of snorting autos; or a boy playing with a dog; or a railroad crew in from a long run, straining their eyes for the signalman's orders. All this requires the trained eye and the artistic sense as well as the trained hand.

For this reason the V.P. ought to have a mechanism which operates with a minimum of complications in opening and getting ready. The closing of the machine may be as leisurely

as one wishes. Therefore a type of machine that requires a carrying case for the protection of the lens is to that extent defective. The case adds one more complication and consumes the fraction of a minute that may be fatal to the picture. Such pictures won't await the photographer's convenience.

On taking the machine from the pocket, the pressure of a button ought to cause the lens to fly into position without further ado. The practice, all well enough with larger cameras, of reaching in and hauling out the bellows by hand and setting the pointer at the distance desired has to be abandoned with the V.P.'s. In the majority of cases the infinity mark is satisfactory, but not always. In fact it is a distinct advantage to have a disc turning arrangement so that the distance can be set wherever desired.

Sometimes you don't want too distinct a background. Take the case above cited of the young lady going across the street. There is no need that every detail on the opposite side of the street should stand out distinctly enough to distract one's attention; signs, Liberty Loan placards, and cabs waiting for fares. To be specific: if you have a $3\frac{1}{2}$ inch lens (as most V.P.'s do) you set the focus at 25 feet, which embraces everything in the field between say 15 and 95 feet with an $f/7.5$ lens; or 15 and 65 with an $f/6.3$. For this reason, the best camera of the V.P. style must allow focussing.

So far as I know, at the present time there is no V.P. camera on the American market embodying all the following desirable features:

- (1) Needs no carrying case for protection of the lens.
- (2) Springs automatically into operating position by pressure of one button.
- (3) Has a focussing arrangement operated by a disc in the lens front.

Some of the V.P.'s offered for sale have two of the three-points mentioned above; some have one, and some, alas! have none.

A V.P. camera requires a good lens, preferably an anastigmat working at about $f/5.6$, more or less. An $f/4.5$ lens requires pretty careful focussing and runs into money. A shutter that would really and truly give say 1-10, 1-25, 1-50 and 1-100 second would be sufficient. Most shutters are, sad to relate, fearful and wonderful liars. But a shutter is something like an astronomical clock; it need not tell the exact truth; what is wanted is to know how much it varies from the truth and arrangements can be made accordingly. By the way, why doesn't some enterprising American make a business of test-

shutters? Some of us would be willing to pay a reasonable price to "know the worst" about a favourite shutter.

The miniature camera naturally suggests the enlarging machine. Pictures can be enlarged, after a fashion, by daylight boxes, but they allow no variation of size or manipulation of printing effects.

At the present time the American manufacturers are woefully behind in enlarging machines; what we have are crude and expensive. It is to be hoped that in due time manufacturers will see the advantage of a first-class artificial light enlarger to keep pace with the small camera. An enlarger is almost a necessary complement to the vest pocket camera.

The V.P. camera will probably never become as popular with the multitude as the larger sizes. The average amateur photographer wants a direct print large enough to see everything distinctly. In the hands of an expert the V.P. will do the very best kind of work and allow an enlargement up to say 5 x 7. It is by no means a toy. In fact one has to graduate from a larger camera in order to be capable of using the vest pocket instrument. But the graduating class is growing every year, and the demands for first-class V.P. cameras will probably be steady and increase in volume year by year.

E. I. C. MOUSE.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Repairing Broken Negatives.

What can there be more annoying than to see a cherished negative lying on the floor in pieces, and how often, I wonder, are those pieces confined to the waste bin. Tempers are ruffled, customers disappointed, orders, money, and business lost; yet, with a little manipulation, the effect of a broken negative catastrophe can be overcome. All the necessary materials for overcoming can, or should be, found amongst any photographer's equipment. These materials consist of two or three grades of retouching pencils, a retouching knife or two, and some spare plates of a medium rapidity.

The method of procedure is as follows, and with ordinary skill the damage can be made good.

First retrieve from the floor or other resting place all the pieces of negative, and then carefully piece them together on a clean piece of glass of a size larger than that of the broken negative. For instance, if one is repairing a half-plate negative, then 7 x 5, or even whole-plate, should be used. Having pieced the broken pieces together, next fasten the outer edges securely to the glass by narrow strips of adhesive binding—Dennison's lantern slide binding, sold in twelve-yard rolls, will be found admirable for the purpose—taking care that other pieces inside are not moved out of position. Our next step is to make a transparency on a medium speed of plate somewhere about H and D 150-180. Transparency making is not at all a difficult undertaking providing one does not "get the wind up" by using too strong an illuminant for making the exposure. I have made hundreds of transparencies by means of an ordinary match—a wax vesta is ideal. Of course, this method is open to criticism, so there is no hard and fast rule why one should adopt this method, but I give it here as a guide for those who are not used to the making of transparencies. The bound-up negative should be placed in a printing-frame with an unexposed plate in contact with it, film to film. It is a good plan to lay a narrow strip of glass round our bound-up negative in the printing-frame to equalise the pressure when the back is put on and fastened down, thus preventing undue pressure on the centre of the frame. Without these strips there is a tendency for the cover to crack, thus adding to one's annoyance by a double catastrophe. Having loaded the frame, stand it end up on the edge of the dark-room bench. Now strike a match, shielding the direct rays from the frame, and when the match is fully alight move it round in a circular motion about six inches away

from the frame so as to ensure as even an illumination as possible. Should one part of the negative be denser than another, the match can be held closer to and opposite the particular part for a moment or two longer than the remainder.

Remove the exposed plate from the frame and develop in any non-staining developer, the borax metol-quinol formula of Messrs Wellington and Ward being very suitable, as it produces negatives and positives of a very fine grain and free from fog or stain. For those who may not have a copy of the formula by them, I give a copy of it here as published in their handbook:—

Water (hot)	20 ounces or	500 c.c.
Borax (powdered)	200 grains or	10 grammes.
Metol	20 ..	1 ..
Hydroquinone	50 ..	2.5 ..
Sodium sulphite	200 ..	10 ..

Dissolve in the order given, allowing each chemical to be in complete solution before adding the next. This developer keeps, by the way, almost indefinitely in well-stoppered bottles.

When our positive is fully developed, fix and wash in the usual manner.

Of course, our positive will show the cracks and lines of breakage, but it is here where the only skill required will come in, and this with the use of a retoucher's knife and pencil. The pencils I prefer are grades 2 and 3, and for work requiring a good black deposit a No. 1 will be useful. The best knives to use for the purpose are those sold by T. S. Preece. Failing these, surgeons' scalpels will be just as useful. The knives most suitable are Nos. 1 and 2, and for fine work a No. 4 is handy to have by you, although a great deal of the work can be done by the first-mentioned grades.

Place the positive on a retouching desk, and with the knife most suitable for the purpose carefully remove the black lines until they are of the same density as the other surrounding parts. This action of reducing the density of these black lines is by the gentle and light process of scraping the film of the positive. On no account should any pressure be used on the knife, otherwise the work will result in a series of rough scratches resulting in an uneven printing density. Take great care not to remove all the gelatine film when scraping, otherwise one will find it very difficult to apply the pencil there afterwards if necessary. Having got rid of the black lines, cover the negative with retouching medium and fill and even up the white spaces with the retouching pencil, preferably by means of cross hatching. If the crack has extended across the face, carefully remove the blemish first with knife, finally finishing off with the pencil. When the positive is worked up and retouched to your satisfaction, varnish it with a good hard drying negative varnish. By varnishing a negative, one not only protects the film from further damage, of scratches, etc., the varnish also tends to even up any work that has been done with either the knife or pencil, and makes it less noticeable in the new negative when made.

A new negative is made by repeating the method adopted for making the contact positive—barring the necessity of fastening the same down on a cover glass. If the knife and pencil work has been carefully done on the positive, our new negative should require very little after work. Should such work be required, repeat the method of treatment of the positive, and, as before, finally varnish.

With a little practice on some old negatives it is surprising what can be done in shorter time than it takes to describe. The whole process is very simple, and an intelligent retoucher can soon convert what appears to be a total loss into an article of value once more.

I might mention here that however carefully the work might have been done, the final negative sometimes looks a little uneven in density owing to the black colour of the pencil work printing a different tone to that of the negative in general. For contact work this is not very detrimental, as the print can easily be evened up in the final spotting, but if enlargements are required the handwork may be rather pronounced.

Should enlargements be required, make a print on glossy bromide about half the size of those required, match up some spotting colour (to which a little gum water has been added) to the exact tone of the glossy print, and carefully spot same, preferably with the aid of a magnifying glass. When completed, copy in the ordinary way.—BENJAMIN F. WELCH.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

- Applications, April 14 to 17:—
- POSTCARD PRINTER.—No. 9,523. Photographic postcard printer. R. N. Kerr and F. W. Tassell.
- DEVELOPING TANK.—No. 9,608. Daylight developing tank for photographic plates. S. G. Killick.
- CINEMATOGRAPHY.—No. 9,788. Cinematographs. A. Page.
- CARBON-HOLDERS.—No. 9,822. Carbon-holders for arc lamps for cinematographs. F. A. Thomassin and G. Williams.

COMPLETE SPECIFICATIONS ACCEPTED,

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

CHANGING BOXES.—No. 120,910 (November 12, 1917). The invention relates to a changing box which allows plates to be changed in daylight. The apparatus comprises a store box, a changing box, and a loading slide. The store box receives in the dark-room the unexposed plates, which, after being exposed in the camera, are replaced in the store box to await development. The store box comprises for this purpose two compartments, one for taking the unexposed plates and the other for receiving the exposed plates. The changing box receives the loading slide charged with the plates, and is put in its place on the camera. The loading slide serves for transporting the unexposed plates from the store box into the changing box, and for bringing the plates back again from the changing box to the store box after

they have been exposed. The loading slide, which is so contrived as to be capable of being separated from the changing box and fitted on to the store box and conversely, constitutes the chief part of the invention.

The loading slide consists of a frame *i*, open on one face, and provided in addition with another opening at the bottom. A handle, *j*, serves for operating this loading slide. The front aperture is closed by means of a sliding shutter, *k*. On the panel opposite to the shutter, inside this slide and at the side thereof, there are pressing members, consisting of arms, *l*, pivoted at *l¹*, and extended by means of springs, *m*. These pressing members serve to ensure the plates, *e*, which are enclosed in the ordinary sheaths, passing out of the slide after the shutter, *k*, is raised. A

sliding member, *n*, provided with lugs or cleats, *n¹*, enables the pressing members to be thrown back for the purpose of rendering the device stationary. This sliding member, *n*, is guided in rectilinear displacements by screws, *o*, engaged in slots, *n*, formed in the sliding member. Charles Rothmeyer, 23, Boulevard Canal, Aulnay-sur-Bois, Seine et Oise, France.

LIVING PORTRAIT PHOTOGRAPHS.—No. 114,173 (August 16, 1917). The invention is an improved method of making the "living portrait" photographs, made by exposure of a plate in separate series of bands through a (shifted) ruled screen.

The positive is made on celluloid, which is mounted on the back of an opening in a front card. A sheet of ruled paper with the lines thereon similar in character to the lines on the screen through which the negative was made is placed on the front of a back card. It will be seen that this method of manufacture is the reverse of the method usually employed.

For keeping the ruled screen in contact with the positive the back card is embossed, so that the central portion of the ruled surface is pressed outwardly into engagement with the inner face of the celluloid positive.

In the drawings there is shown a back card or mount 50, the front of which is printed or attached ruled lines 51. In front of the back card is the front card or mount 52, having an oval or other opening therein, and at the back of the front card

Fig. 1.

Fig. 3.

attached a celluloid positive 53, having the banded pictures thereon. Flexible strips 54 and 55 of fabric are attached to the edges of the cards for the purpose of binding the two cards together and also allowing lateral movement of one card relative to the other. The placing of the ruled lines 51 on the back card 50, and the placing of the celluloid positive 53 on the back of the front card 52, results in an animated photograph that is free from shadows. In Figs. 3 and 4 there is shown an improved back card for use in the manufacture of animated photographs. While the structure illustrated in Figs. 1 and 2 is efficient, it has been found that with use the flexible connecting strips 54 and 55 stretch, and it is

Fig. 2.

Fig. 4.

necessary to press the back card into engagement with the back of the front card in order to get the best results. To avoid this difficulty the back card is embossed in the manner shown, the embossed portion being designated by the numeral 56. With this construction the front and rear cards are grasped naturally between the thumbs and forefingers to manipulate the cards and display the pictures. Reginald Ignatius Atherton, 16, Cavendish Avenue, Church End, Finchley, London, N.W.; David Burne Jones, 6, Lansdowne Grove, Neasden, London, N.W.; and Sidney Croneen, 67, Hornsey Lane, London, N.

DISTORTED PHOTOGRAPHS.—No. 116,727 (October 3, 1917). In producing, by photography, a humorous picture or series of pictures a non-spherical lens or a lens formed of two or more portions optically diverse from one another is so mounted that it may be rotated about an axis transverse to its general plane. The lens

may be fitted to a cinematographic camera and rotated during the exposure.

One method of carrying out the invention is shown in the drawing. The method may be carried into effect by a camera fitted with a lens such as that indicated at K in the drawing. This lens is composite, being formed of three distinct portions, which may either be integral with one another or formed separately from one another, and suitably cemented together. Each portion is different from the other in its optical value; thus the portion K¹ may be of spherical formation with a positive curvature, the portion K² of cylindrical formation with a positive curvature, and the portion K³ have a value differing both from that of the portion

K¹ and that of the portion K². Any combination of diverse curvatures may be employed, and any number of distinct portions may be used in the lens. Diversity may be obtained merely by diversity in degree of curvature or by diversity in degree as well as in kind.

In order to enhance the humorous character of the photographs when a series is to be taken, the lens is rotated about the centre, K⁴, and exposures taken through the lens in successive positions thereof. Thus, for example, for a cinematograph film the lens is slowly rotated while the object to be photographed performs movements before the camera. The lens may be a simple cylindrical lens, and be rotated about an axis transverse to the axis of the cylinder. William Henry Baker, 32, Hatton Garden, London, and William Millward, 34, Butler Street, Chorlton-on-Medlock, Manchester.

CINEMATOGRAPH FILM.—No. 117,887 (February 8, 1918). This invention consists in a film the edges of which are reinforced by sewing to them adjacent to the feed openings one or more continuous threads of silk, cotton, or the like, which effectively prevent the edges of the whole film from getting torn. Hubert Degens, Maastrichterlaan 45, Vaals, Holland.

AERIAL PHOTOGRAPHY.—No. 115,136 (June 27, 1917). The invention consists in arranging a camera in or upon a frame or structure so that it is capable of movement therein (at a rate which may be adjustable), and in adapting the camera to travel over a stationary screen or shutter having an aperture to give the required time of exposure, so that when taking a photograph the camera may be set to travel at such a speed that it will at the moment of exposure of the photographic plate be stationary, or moving only with a low velocity relatively to the object being photographed.

In the drawing, the camera *a* is mounted in a slide-like manner upon a frame which may consist of guide rails or rods *b*, a

stationary shutter *c* being arranged in the frame and clipped thereto, so that it comes between the lens and the photographic

plate, but adjacent to the latter in order to give the advantages of a focal-plane shutter. The gap or slot *c*¹ in the shutter is proportioned so as to give the required time of exposure. The camera is moved over the shutter at a speed which may be adjustable, by springs, compressed air, or other means, buffers and other devices being employed to bring it to rest and also to prevent recoil at the end of its traverse. In the figures, compression coil springs *e* assisted by a spring-rotated drum *f* acting on the camera through a flexible element, serve to traverse the camera from right to left. The springs *h* serve as buffers to bring the camera to rest without shock. Edgar Duerr, Bella Vista, Langham Road, Bowdon, Cheshire.

Trade Names and Marks.

REGISTRATIONS RENEWED.

TRAIN AND CAMERA (Design).—Nos. 271,453-4. Registered by the Paget Prize Plate Co., Limited, in 1905. (Classes I and 39.)

NOBRAH.—No. 272,979. Registered by Kodak, Limited, in 1905. (Class I.)

TRADE MARKS REMOVED FROM REGISTER.

In the official language of the "Trade Marks Journal" the following trade marks have been removed from the register through non-payment of renewal fees. Such non-payment is, of course, the method adopted by a firm having no further occasion for the use of a mark:—

ROYAL PHOTOGRAPHIC SOCIETY

MEETING held Tuesday, April 29. Mr. T. H. B. Scott in the chair. A lantern lecture was delivered by Mr. W. J. Roffey on the "Cathedrals of Ely, Litchfield, Gloucester, and Wales." Mr. Roffey, to the accompaniment of a large number of excellent lantern transparencies, discoursed on the architectural and historical features of his ecclesiastical subjects. On the proposition of the chairman a hearty vote of thanks was accorded to him.

CROYDON CAMERA CLUB.

The Easter Monday outing proved a great success, a large party walking from Kingswood to Buckland, where an excellent tea was provided. Once on the heath, Mr. Harpur soon dug himself in, and with reflex perched on a three-inch tripod bagged many a foreground study full of that elongated perspective which, owing to a naturalistic viewpoint, should make an irresistible appeal to any centipede or other ground insect with artistic perception. Mr. Johnson early in the day smashed his focussing screen, and went out of action with most of his plates undamaged. So did another member, owing to his "Compound" shutter refusing to work at any other speed than 1/250th sec. Mr. Walker's auspicious disaster for the day fully maintained his reputation, for the mirror of

his up-to-date reflex insisted on executing a lunatic jazz step on every attempt to operate the shutter release. The Rev. Le Warne must be credited with identifying at a distance of over a mile a Postleby known to exist, but up to then undetected by anxious eyes. "A far, far better thing," etc.

The following Wednesday, Mr. Cavendish Morton gave a lecture on "Discrimination," a subject of immense scope, as was fully admitted. Possessed of real oratorical gifts and a keen analytical faculty, which an emotional method of delivery emphasised in the sense that it compelled attention, the electrical atmosphere created is most difficult to describe, but may be suggested as being in the nature of "complex variations on a theme." Strictly modern in treatment, crashing chords broke in on *pianissimo*, and, amidst general harmonies, fresh *motif* followed on *motif* in somewhat bewildering fashion. Or, expressed in another way—"denunciation" followed so quickly on "appreciation," pathos on humour, sorrow on joy, as to induce a sort of mental switchback condition, with the peculiar feeling of exhilaration such engenders.

The lecture, which was crammed full of good things, including elegant aphorisms and neat definitions, was delivered without even headings to refer to. Meticulous accuracy is therefore not guaranteed in the following notes. All problems, artistic, social, moral, and scientific, were approached on the *dynamic* side: that was insisted upon, and no one raised an objection. Many a definition of "Art," he said, existed, the best one, in his opinion, being: "The seizing of the living truth in the natural, and the finding it still alive in the artificial." Here a member, who has shown signs of mental strain owing to a surfeit of words on the subject during the session, was distinctly heard to say, "Damn art!" "I hope I am not interrupting you," politely said the lecturer. "Not at all," was the equally urbane reply.

Wisdom, Mr. Cavendish Morton continued, can often be found in babes and sucklings, and gave a pleasing illustration in the person of a little son who is evidently a chip of the old block. After a consideration of the theory of "vital activity," the labour troubles were dealt with, the unrest, he thought, being mainly due to "stultified aspirations." Cinematographs came next, which, he deeply regretted, were often misused. Still on the dynamic aspect, the wonderful skill of Inman and Paganini were alluded to, and the psychology of composer and artist were analysed, with his friend the late Coleridge Taylor and Turner as examples. Personally, he considered himself a malignant failure as a professional photographer by attempting to combine a hobby with business. The only satisfied soul in the world was the tinker, a statement which obviously overlooked many an artist of the camera. Dynamics changed to the thunder of dynamite when he turned to "jazz," generated by the worst types of American criminals, and it was appalling that victory should be celebrated in such an abominable way.

Let it be known once and for all, for so it was said, that the creation of fashions in women's dress is spontaneous, born of a desire by the sex to express itself in clothing. Clothing is good so far as it reveals character and movements of the figure, and bad so far as it conceals them, a definition which should cheer the lady revue artist. He then introduced what was apparently the Greek "Doric dress," a square of fine cloth with marginal design, and showed its many graceful applications. When made of thin material it was often employed held up as a background to set off the figure (other clothes were worn). Clothed in the garment, Mr. Cavendish Morton recited in impressive and dramatic manner some lines from Keats' exquisite "Ode to Melancholy," with appropriate variations of posture and the folds of the costume. And so ended the most sensational evening since the secretary, in a state of semi-nudity, gave his demonstration on "physical exercises." One appealed to the mind, the other to the body. A most hearty vote of thanks was accorded for a lecture of exceptional interest, stage-managed in first-class style by an experienced hand—one who now, happily for the club, becomes a new member.

FORTHCOMING EXHIBITIONS.

April 17 to May 22.—Hammersmith Hampshire House Photographic Society Annual Exhibition. Two open classes. Joint secretaries, J. G. Abrahams, 41, Hamilton Terrace, London, N.W.8; A. H. Page, 12, Lime Grove, London, W.12.

Commercial & Legal Intelligence.

LEGAL NOTICES.—Notice is given of the dissolution of the partnership (by mutual consent) between Sydney Harold Leveton and Alchanaan Cohen, carrying on business as photographic apparatus makers, at 78, Digbeth, Birmingham, under the style of Cohen and Leveton.

NEW COMPANIES.

NASH, KENYON AND CO., LTD.—This private company was registered on April 19 with a capital of £3,000 in £1 shares. Objects: To take over the photographic department of J. R. Cave, Ltd., formerly carried on by that company and more recently by J. Wilson, at 169, Lord Street, Southport. The first directors are: J. Wilson, 9, Harrod Drive, Southport, gentleman; H. Nash, 141, Sussex Road, Southport, photographer, etc.; H. Kenyon, 46, Sussex Road, Southport, photographer. Registered office: 169, Lord Street, Southport.

News and Notes.

MESSRS. A. C. GRUNDY AND SONS, trade printers, advise us that they have removed from Rickmansworth to 12, Grand Parade, St. Leonards-on-Sea.

THE PHOTOGRAPHIC CONVENTION.—It was decided at a council meeting held at Anderton's Hotel, London, E.C., on the 24th ult., to hold a meeting of the Photographic Convention of the United Kingdom this year. The date fixed is the week commencing July 7. It being impossible for the gathering to take place in France, as was intended, the Continental Convention is postponed, and efforts are to be made to make either Oxford or Warwick the centre for the 1919 meeting. Members will be informed by post and announcements made in the Press as soon as the necessary arrangements have been made. Cambridge was also named, but the voting was in favour of the "Dark Blues."

DEATH OF A NOTED AUSTRALIAN PHOTOGRAPHER.—Australian newspapers just to hand announce the death of one of the best known photographers in the Commonwealth—namely, W. H. Hammer, who died a few weeks ago at Norwood, South Australia. He was the principal of the old-established firm of Hammer and Co., and partner and director of Studio, Ltd. Born at St. Austell, in Cornwall, seventy-four years ago, he went out to Australia in the year 1880, started a photographic business in Adelaide, and was most successful. His great hobby was music, and the Australian papers state that before leaving England he was known throughout Cornwall as an organist and conductor of choirs and bands.

THE PHOTOGRAPHIC ARM.—An official synopsis of the work of the Air Force in the war gives the following particulars of the great work of the photographic section:—

The original and, at first, the only duty of the aeroplane in war was reconnaissance, and the earliest reconnaissance reports were of the utmost value. The information gained immediately prior to and during the retreat from Mons in 1914 was of the greatest possible assistance to the British and French Armies. The effect of regular, rapid, and accurate reconnaissance at once made itself apparent.

With the development of trench warfare it became necessary to supplement reconnaissance reports by full information as to the position of enemy trenches and the location of his batteries. In November, 1914, the first successful aerial photograph was taken of the village of Neuve Chapelle. During the early experimental stages, photographs were taken at an altitude of 3,000 feet, but the rapid development of anti-aircraft fire has forced the aerial photographer to an altitude of 22,000 feet.

During the first month that the photographic section operated in France only 40 negatives were taken. During October, 1918, 23,247 negatives were exposed, and approximately 650,000 prints were issued. A high standard of photographic work has been reached, and whole areas of country, lines of railway, and trench systems have been photographed and accurate maps prepared.

The photographic section in 1914 consisted of two officers and three other ranks. Their outfit comprised two cameras and a port-

able box of developing chemicals. The photographic *personnel* at the present day consists of 250 officers and 3,000 other ranks, distributed throughout all theatres in which photographic work is carried out, and a large training school of photography has been formed at Farnborough. Up to September of this year as many as 5,287,826 prints of aerial photographs had been issued by the Air Service in the field.

THE FIXING OF BROMIDE PRINTS.

To the Editors.

Gentlemen.—In reference to the three different articles that appeared in your issue of April 18 dealing with this subject, my experience is this (and I print many thousands annually):—I print strips of six. I never put more than two strips in the developer at once. When development is complete the strip is taken in the fingers by each end, and with a curving sweep is quickly passed through a dish of cold water, and immediately placed in the fixing-bath, face up. The dish is then rocked once or twice to wash off any of the developer which may still be left. Then the strip is turned face down. In my opinion the small black spots which are sometimes left on prints are caused, not by air-bells, but by small quantities of developer left on. I find that three heaped table-spoonfuls of hypo—which will weigh about 4 ozs.—will fix thirty-six six-quarter sheets without any danger of staining the cards. I do not measure the water; just use sufficient to cover the cards. After this quantity of strips has been passed through, two or three more spoonfuls are added to the bath. Working on this plan, I have very few stained prints.

THOS. HENDERSON

THE LATE SIR WILLIAM CROOKES

To the Editors.

Gentlemen.—Having been intimately associated with the late Sir William Crookes for a great number of years and published several papers with him on a variety of photographic subjects, commencing with early attempts to preserve the sensitiveness of collodion plates (1854), I read with interest your brief notice appearing at page 189 of April 11 issue.

I well remember our portraits being taken together by Messrs. Hermann and Malone, copy of which you reproduce. This was taken in their studio occupying the upper premises of John Newman, optician, of Regent Street. Crookes and I were fellow students then at the Royal College of Chemistry, and later both were promoted to become Dr. Hofmann's assistants in the general laboratory at Oxford Street. Our moist films were quickly superseded by Dr. Hill Norris's collodio-bromide process, which came to stay.

Crookes and I took a wonderful series of solar eclipse photographs in March, 1854, and July, 1860, through an improvised camera attached to the Woolwich telescope, before this work was regularly undertaken by Glaisher at the Greenwich Observatory.

To get material for his examination of thallium it was necessary to distil considerable quantities of a special brand of Spanish pyrites, and a furnace was set up at Brook Green, Hammersmith (the family residence), and worked continuously, I taking part with him in the night watch. On another occasion we were at work on selenium and the seleno-cyanides—results published in the "Quarterly Journal of the Chemical Society." In fact, so intimately were we associated that I was "best man" at his wedding, which took place at St. Pancras Church on April 10, 1856.—Yours very truly,

Canonbury, April 29.

JOHN SPILLER

PRESS v. PROFESSIONAL PHOTOGRAPHERS

To the Editors.

Gentlemen.—In the current issue of a weekly journal published in the interests of the workers in the newspaper world is a paragraph which concerns the welfare and social standing of the average professional photographer, and as few of your readers may see it, I beg to call particular attention to it, as well as to the editorial comment that foots it.

The paragraph in question reads thus: "A problem that is becoming increasingly insistent for newspaper photographers is the clashing with professional photographers at public functions. The latter frequently come by appointment, and, in effect, monopolise the subject." This is apparently a contributed paragraph, and the complaint of an enterprising pressman who has struck trouble, as at the foot of the wail appears the following editorial comment: "We do not see why several cameras should not be staged simultaneously. This is done in snapshotting, and could equally be done in a more formal setting."

The editorial comment, I think, evidences a lamentable lack of knowledge of a professional photographer's business, and is apt to encourage the already too precocious newspaper photographer to be a greater nuisance than he sometimes is to-day at happenings to which a legitimate professional worker has been specially invited.

In the case of a special invitation, i.e., "by appointment," I have an idea that the invited photographer has a perfect right to "monopolise" the subject, and I for one shall continue to do so in spite of any interlopers who are present without being invited.

I am looked upon as being a harmless kind of individual, but should any chance press photographer "stage" his camera alongside mine, in front of a group of my own posing, when he has been requested by me not to do so, there will be trouble.

If no special invitation has been given me or anyone else, I am willing to take my chance with the rest and to get what I can as "a sport" but a newspaper photographer has, in my humble opinion, no right to make an exposure upon any group I have been "appointed" to pose. So let us have fair play.—Yours truly,

L. T. W.

NEW SIZES OF SMALL CAMERAS AND PLATES THEREFOR

To the Editors.

Gentlemen.—The announcement "Quarter-plates to Go," in your issue of 25th ult. will bring home to photographers with more force than ever the fact that they are gradually, but surely, coming under the complete domination of the plate trust, unless indeed this last arbitrary and indefensible action is but a subtle move on the part of the British Photographic Manufacturers' Association to increase the sale of new apparatus by what amounts to the compulsory scrapping of everything essential to the quarter-plate size. The quarter plate is as much a standard British size as the whole-plate, as it is actually a quarter of a whole-plate, whereas the so-called half plate belies its name. Presumably, however, it is not proposed to abolish the two last named sizes for fear of the profession being at last goaded into starting a co-operative plate factory.

Notwithstanding the numerous "toy" sizes introduced with but little reason during the past few years, the quarter-plate undoubtedly remains the favourite amateur size in this country. There must be hundreds of thousands of quarter-plate cameras in existence, a large proportion being of high class make and good for long years of wear. In addition, there are countless slides, printing frames, dishes, racks, etc., that will be rendered useless by this last step of the plate makers, and it must also not be forgotten that hardly any quarter-plate enlargers will take the proposed new size, 8 by 12 cm. (roughly, 3½ in. by 4½ in.)

It is difficult to understand how the abolition of the quarter-plate will prevent waste of material, as I was told some years ago by the manager of a dry-plate works that it was the trade custom to coat whole-plate glass and cut it into four. He also said the "toy" sizes then coming into vogue were welcomed as using up what would otherwise be waste glass. It would probably be impossible to find a parallel in the history of any other industry whereby apparatus representing an enormous aggregate value has been condemned to the scrap-heap by such ruthless action and on such flimsy pretext.—Yours faithfully,

OLD HAND.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

W. F.—If you cannot remove the brown substance by very gently rubbing the lens with a bit of soft old cambric wetted with pure alcohol (spirits of wine), we think it would be necessary for you to send it to an optical firm. No doubt one or other of the lens makers could now undertake such a little job as this.

R. W. C.—If you do not carry on the business in your own name, you are required by the Business Names Act to register it at the cost of 5s. per annum, and to comply with the regulations affecting such registered businesses. The forms should be obtainable from every post office; if not, from the Registrar of Business Names, 59, Russell Square, London, W.C.

A. E.—The smallest size in which a reflex camera is made, apart from a small exceptional pattern of Kodak reflex (not now, we believe, on the market), is $3\frac{1}{2}$ by $2\frac{1}{2}$ inches. The "Soho" of this size measures $6\frac{1}{2}$ by $6\frac{1}{2}$ inches when closed. We believe Messrs. Adams and Messrs. Newman and Guardia also make a reflex of this size; probably that of the former would be a little smaller, and that of the latter a little larger, than these dimensions just given.

B. J. K.—The minimum fee for reproduction is 10s. 6d., from which the agents would deduct their commission, but we should think they would be able to place the photographs more successfully than you could by offering them direct to the newspapers. Glossy bromide prints are generally used for Press photographs, and we should say are preferable nowadays to toned P.O.P. We think it very unlikely that you would be able to dispose of the negatives for lecture or other purposes.

A. C.—(1) Ordinary plate glass or heavy window glass is generally used for glazing postcards. The size varies considerably, but for work on a large scale sheets about 3 feet by 18 inches are very commonly used. (2) About the only possible substitute for metal for the development of prints and postcards is amidol, made up according to the usual formula. (3) Ox-gall is one of the very best glazing solutions, and if purchased in the purified form, sold by Messrs. Rheinlander and Sons, New Malden, Surrey, is most effective in use.

J. M.—Metal skin poisoning is a very individual complaint, with the result that what is a remedy for one person is useless for another. The first thing is that anyone afflicted with this complaint should discontinue the use of the developer, and, apart from developing the general health, should take steps to keep the skin in a soft and, we think, slightly acid condition. Ointments which have been very well spoken of for this particular complaint are those known as Ujah and sold by the Ujah Ointment Company, Clarendon Street, Oxford, and as Sphagnol, sold by Peat Products, Ltd., 13, 19, Queenhithe, E.C.4.

A. L.—These sensitive buttons are almost entirely imported from America, and are included among the photographic goods, importation of which is prohibited. If you cannot obtain them from

Messrs. Fallowfield, we are afraid you will have to regard them as unobtainable. A developing formula is as follows:—

Soda Sulphite, cryst.	31 parts.
Hypo	248 "
Soda carbonate, cryst.	8 "
Potass. bromide	8 "
Water	800 "
Hydroquinone	20 "
Ammonia (sp. gr. 91)	45 "

J. H.—There is almost certainly copyright (the property of someone) in the Royal group, and probably also in that of Disraeli's cabinet, for the reason, in the latter case, that such engravings are almost always made from a painting, and copyright in the latter originally lasted for the life of the artist and seven years after his death, and is further perpetuated by the Act which came into force in 1912. Thus, even though you may not copy the original, you are infringing copyright in it by copying the engraving. You do not say what you propose doing with the copies. If only one or two copies are made, say, for a lecture, any use of this kind is permissible under the new Act, but if copies are to be issued and sold in numbers we think that you render yourself liable for action if the thing comes under the notice of the owners of the rights in the works.

J. K.—(1) So far as we know there is no Customs duty, but we understand that there certainly is at present a restriction on importation. We believe the matter is being taken up by the company, and you had better apply to them for information as to whether they can still export the apparatus. (2) We have not the means of judging what view the Ministry of Labour Committees take as to what is and what is not a retail business, but we should imagine that trade retouching would not be considered such, nor, we should think, would the making of views or commercial photographs. But in the case of a sticky-back business we should imagine that certainly would be regarded as a retail business. Impossible for us to say how long the restrictions will be maintained. From the fact that they have recently been reorganised within the Ministry of Labour, we should imagine that the intention is to keep them in operation for at any rate some time.

The British Journal of Photography.

Line Advertisements. Charges for Insertion.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind the scale of charges. They will thus save themselves delay in the publication of their announcements. A Schedule by which an advertisement can be correctly priced will be sent on request.

Net Prepaid Line Advertisements.

12 words or less	1/-
Extra words	1d. per word.

(No reduction for a series.)

Special Note. Box Number Advertisements.

"Box No." and office address charged as 6 words.
For forwarding replies add 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.
Orders to repeat an advertisement must be accompanied by the advertisement as previously printed.
Advertisements are not accepted over the telephone or by telegram.
The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.
Displayed Adv'ts should reach the Publishers on Monday morning.
The insertion of an Advertisement in any definite issue cannot be guaranteed.

SUMMARY.

The papers contributed to a recent meeting of the Royal Photographic Society as a symposium of progress in the production of lenses for aerial photography represented the achievements in this field of Messrs. Taylor, Taylor and Holson, Ross, Limited, and Aldis Brothers. Mr. Appleton, for the first-named firm, deals with the measures taken for the design of a lens of greatly reduced comatic error and yielding the crisp and "relief" definition required in aerial negatives. Mr. Hasselkorn, of Ross, Limited, describes modifications made in the Ross Xpress for aerial work, as also a new and simple type of *f/6* aerial lens. (P. 243.)

A note by Mr. Harvey Collingridge, B.Sc., deals with the optical conditions in true-to-nature photography, and contains a chart designed to indicate what they are in a given case. (P. 249.)

A system of measurement of sensitiveness of plates to X-rays is contained in a recent paper before the Royal Society of Victoria. (P. 250.)

In "Photo-Mechanical Notes" (which we hope now to publish again at frequent intervals) the writer deals with the storage of films, stripped from wet-collodion negatives, with repeat orders for engravings and with rotary photogravure from flat plates. (P. 252.)

The use of a lens of long focus in the photographing of motor-cars is a necessary means of avoiding exaggerated size of the lens and corresponding dwarfing of the body. (P. 242.)

Formulae for line development with Monometh-hydroquinone are published by the White Band Manufacturing Company. (P. 250.)

In his article this week "Practicus" deals with the commercial considerations concerned in the sale of enlargements in a portrait business, pointing out the necessity for superiority of quality and the opportunities for the sale of costly enlargements which are presented to even a middle-class business. (P. 247.)

The Order, under the Defence of the Realm Act, requiring a licence for the starting of a new retail business is still in force, and likely to continue so for some time. Some notes for the guidance of those applying for licences will be found on page 242.

A contributor to "Assistants' Notes" gives tables, showing the wastage in enlarging negatives of the present standard sizes on to papers of sizes ranging from half-plate to 20 by 16. (P. 251.)

Sydney papers have recently published figures showing the continuous prosperity of the Kodak (Australasia) Company. (P. 250.)

An apparatus trimming both edges at once of a photograph or mount is among the patents of the week. (P. 252.)

As a system of producing portrait prints the enlargement of small negatives made on the rapid portrait plate can be overdone. (P. 242.)

EX CATHEDRA.

Colonial and Foreign. In referring briefly last week to the issue of June 6 next of the special Colonial and Foreign number of the "British Journal" we laid emphasis upon the particular feature of its distribution, in an extra edition of 5,000 copies, throughout the British Empire abroad and in foreign countries. These direct recipients of the issue have their names and addresses filed at this office in a list which is scrupulously corrected and revised from year to year in correspondence with changes which are notified to us directly by the people concerned or through the copies being returned by the Post Office. The list is thus an up-to-date one, and practically every copy of the extra edition reaches its addressee. Of the foreign countries to which copies are sent the following are of special interest at the present time:—

Argentina	Jamaica
Brazil	Japan
Burma	Mexico
China	Malay Peninsula
Colombia	Peru
Dutch East Indies	United States
Egypt	Uruguay
Guatemala	Venezuela

It would seem that the forthcoming "B.J. Special" will contain a heavy weight of announcements from advertisers who, since the outbreak of war, have been able by means of its predecessors to keep their names before consumers in these countries whilst enemy competitors have been cut off from their European sources of supply. With the removal of restrictions on trade it cannot be doubted that British firms will claim a large share of custom which has accumulated during these years, and are taking this first opportunity of announcing their peace-time resources to the foreign buyer. The forthcoming special issue will likewise carry the messages of British manufacturing and exporting houses to the widely separated places of the British Empire. There is scarcely a corner of Africa to which copies are not sent, and they go in particular to Cape Colony, the Orange River Colony, Rhodesia, Natal, and the Transvaal. Australasia receives a considerable proportion, the lists of recipients being classified under New South Wales, Queensland, South Australia, Victoria, Western Australia, Tasmania, and New Zealand, whilst there is even a sprinkling in the Sandwich, Fiji, and other Pacific Island groups. British North America figures prominently in these lists, which mark the regularly increasing establishment of portrait and commercial photographers in Quebec, New Brunswick, Nova Scotia, and Newfoundland, Ontario, Alberta, and Manitoba, and British Columbia. And when we have mentioned the Indian Empire there still remain a host of far-off minor states, islands, and places to the largely isolated photo-

graphic buyers in which the forthcoming issue is sent. Announcement of the last day for the receipt of advertisements will be made in due course, but early intimation of space requirements is advised.

* * *

Sensitising Carbon Tissue.

Carbon printing is not so generally used as it might be, on account of the difficulty which some workers find in sensitising the tissue. When ready-sensitised tissue can be obtained this trouble does not arise, but many people find it inconvenient to wait for supplies, and moreover often require only one or two pieces of a special colour. The only course, therefore, is to keep a small assortment of various colours of tissue in stock, and to sensitise as required. This may readily be done with a spirit sensitiser, but we much prefer sensitising in the usual 3 to 5 per cent. bichromate bath, and squeegeeing the tissue upon ferrotype plates to dry. This protects the surface from gas, coke-stove, or other deleterious fumes, and also gives a perfectly flat and polished surface to the gelatine, making it much easier to secure contact with the negative than when the tissue is allowed to dry. The total time necessary for sensitising and squeegeeing a dozen pieces of tissue need not exceed twenty minutes, and after that nothing more is to be done until the tissue is filled into the frames. No special precautions against light are needed while sensitising, but the sheet when on the ferrotype should be kept in as subdued a light as possible. In a warm room they will dry in three or four hours, and then one must take care that if they drop off the ferrotype they are at once transferred to a light-tight box or calcium tube.

* * *

Perspective in Catalogue Photographs.

We have been struck by the many catalogue illustrations we see which lose much of their advertising value because of the violent perspective of the photograph, usually due to the quite unnecessary use by the photographer of a lens of too short focus. For example, photographs of motor-cars are nearly always made with a lens that gives a picture showing the bonnet of the engine enormous and a diminutive car body, which latter surely should interest the prospective purchaser most. We quite understand that the manufacturer of the car is apt unconsciously to lay stress on the mechanical features of his car, and therefore he must be expected to insist upon a point of view in which the engine, though covered, is prominent, but at the same time he does not want his picture of a limousine, for instance to look as though it were meant for dwarfs with a giant driver, and the back wheels to look half the size of the front ones. This is the photographer's fault, and he might still retain the same point of view and also give correct perspective if he would only use a longer focus lens and get farther away from the subject. What we say of motor-cars holds true of most other large objects that are photographed for catalogues—furniture, pianos, machinery, and so on.

* * *

Grain and Enlarging.

While we have no wish to underestimate the value of the enlarging process, there is no doubt that many of the results that are seen in professional show cases are decidedly over-enlarged. Many photographers seem to think that if only the definition of the negative is good, there is really no limit to the size of the enlargement that may be made from it. In landscape or similar work perhaps that may be so, but in portrait photography there are limits beyond which the negative will not make an enlargement of good technical quality by reason of the grain of the plate.

While improvements in this respect have been many, it is still impossible that a plate of studio rapidity can be as fine grained as one with a speed of perhaps 80 H. and D. Any photographer who doubts the truth of this assertion need only take one of his average portrait negatives and another on a fine-grained slow plate and have an enlargement made from each. We have little doubt that enlargement will be most free from granularity. No matter what many photographic writers may say, the small camera will never for this reason be universally adopted for studio work, for it is almost a literal impossibility to enlarge, say, from $2\frac{1}{4} \times 1\frac{1}{2}$ to 12×10 without the complexion of the sitter having the texture of a stucco wall or concrete floor. Many of our best portraitists still adhere wholly to contact work, and such a course is amply justified by their results. To be well within the limit of freedom from granularity enlargement to not more than two or three diameters may be prescribed as advisable practice, sufficing also for practical and commercial conditions.

LICENCES FOR NEW RETAIL BUSINESSES.

THE Order issued in February of last year under the Defence of the Realm Act in reference to the establishment of new retail businesses is one which is still in force, and looks as though it would remain in force for a good time yet. Naturally, as a result of demobilisation, a great many men now find it necessary to comply with the terms of the Order in setting up for themselves in business. Scarcely a day passes but we receive several applications for information as to the course which must be followed. We referred to the terms of the Order some months ago, but since, apparently, it is only until quite recently that advice in regard to it is being widely sought, we may advisedly deal with it again. It should be understood at the outset that at the time of its issue, and still more at the present time, the Order was and is designed for the protection of men who have been compelled through their joining the Services to close down their own businesses—retail businesses, that is, in which the dealings are with the general public. The Order does not apply to businesses in which the customers are "trade"—that is to say, businesses in which the goods are sold to, or work done for, persons in a particular trade. The object of the Order is to prevent persons stepping into the shoes of men who have voluntarily or compulsorily closed their businesses, and therefore those who have done so and are now making application for licence to revive a business which has been discontinued or to open elsewhere should make it clear that their service with the Army or Navy has necessitated this course.

The Order applies not only to the establishment of a new retail business, but also to the addition, to an existing retail trade or business, of a new branch. Such a provision is a very necessary one for the prevention of evasion of the terms of the Order. Nevertheless, it is also one which at times may bear hardly upon a genuine applicant. For example, a man who has been demobilised wishes to obtain a licence for the establishment of a photographer's business, and may wish also to add to the latter that of making and supply of picture frames. A purely official department very likely may raise an objection, but we think that an applicant should have no difficulty in showing that such a side line, even if it was not part of the business which he formerly carried on, is so commonly a part of an ordinary photographer's business that it cannot be regarded as the addition of a distinct branch of trade.

Originally under the administration of the Ministry of National Service, the Order has now passed to the Ministry of Labour, and is in the hands of eleven offices distri-

buted, ten of them in England, one in Wales, and one in Scotland. The Order apparently does not apply to Ireland; if it does, at any rate we have no knowledge of its administration there. Therefore, any applicant who is starting or re-starting a retail business requires to address the office covering the district in which the business will be situated. The address of the applicant is of no concern in this respect, since the function of the office is to carry out investigation by its staff of the conditions in the town or quarter where the business is to be established, and therefore the application requires to be made to the office most accessible. The addresses of these licensing offices are given below. Inquiries should be made in writing to the Secretary (New Business Licences).

London and South-Eastern (City and Metropolitan Police District, Kent, Surrey, Sussex).—Hotel Windsor, Victoria Street, London, S.W.1.

South-Western (Gloucester, Wilts, Dorset, Somerset, Devon, Cornwall, Hants, Isle of Wight).—5A, Union Street, Bristol.

Yorks and East Midlands (Notts, Yorks (excluding Cleveland), Derby (excluding Glossop and New Mills), Lincoln).—Harewood Barracks, Woodhouse Lane, Leeds.

West Midlands (Staffs, Shropshire, Hereford, Worcester, Warwick).—Queen's College, Paradise Street, Birmingham.

South Midlands and Eastern (Norfolk, Suffolk, Cambridge, Oxford, Huntingdon, Bedford, Berks, Bucks, Northants, Leicestershire, Rutland, Herts, Essex).—80, Westbourne Terrace, Paddington.

North-Western (Lancashire, Cheshire, Derbyshire (Glossop and New Mills District), Isle of Man).—New Arts Buildings, Liverpool.

Northern (Northumberland, Durham, Cumberland, Westmorland, Yorkshire (Cleveland District)).—47, Pilgrim Street, Newcastle-on-Tyne.

Wales (all Wales and Monmouthshire).—27, Bute Street, Cardiff. Scotland (all Scotland).—15, Athol Crescent, Edinburgh.

A good deal of disappointment is quite naturally felt at the length of time which elapses before the licence is granted, but the Ministry of Labour has recently sought to justify the slowness of the process by stating that applications are being received to the number of about 2,500 per week, of which about 2,000 are granted. Probably the apology has its justification in fact. It can be readily understood that if anything like an adequate investigation is made of each of the 200 odd applications at each of the eleven branches, for this alone time is bound to be taken up, apart from the reference of the cases back for the decision of the Advisory Committees which recommend the granting or refusal of the applications.

THE DEVELOPMENT OF BRITISH LENSES FOR AIRCRAFT PHOTOGRAPHY.

[The meeting of the Royal Photographic Society held a month or two ago provided a very notable demonstration of the achievements of British lens makers in the production of objectives answering to the very critical requirements in the way of definition and brilliancy of the R.A.F. Photographic Section. The papers which we reprint from the Society's "Journal," usefully emphasize the success which attended the efforts of British opticians, a success the more remarkable when the handicapping conditions, the chief of which was the restricted variety of optical glasses, are recognised. Unfortunately, half-tone reproduction on news paper does not suffice to show the really very marked superiority in definition and covering power of these British lenses in comparison with those of enemy manufacture of equal focal length. But the technical information given by the representative of the three optical firms which contributed to the meeting will be read with interest. The three firms represented are Messrs. Taylor, Taylor, and Hobson (Mr. W. B. Appleton), Messrs. Ross, Limited (Mr. J. Hasselkus), and Messrs. Aldis Brothers (authorship of the paper not stated).—Eds. "B. J."]

JUDGING from letters which have appeared recently in the photographic journals, there is a general desire among dealers in, and users of, photographic lenses, that the merits of lenses of British make should be clearly placed before the public, and I hope that the information given by me and others will serve that purpose. As one who has a great admiration for beautiful work, I do not under-estimate the excellence, both in design and execution, of the best lenses of German manufacture, but I hope the facts and comparisons which I shall presently give will make it abundantly clear that there is no longer any excuse for the public to buy German lenses in the belief that they are the best.

It may interest members to hear fuller particulars than were given in last year's Presidential address, of how my firm's lenses were brought into such close competition with the celebrated I. C. Tessar. It may be remembered that when there was a shortage of lenses suitable for the Air Service, a public appeal was made for certain lenses of specified focus and aperture, which were known to be suitable for Service requirements. At that time Taylor, Taylor, and Hobson, Ltd., had already supplied the Service with large quantities of Cooke lenses, and were rather surprised that these were not asked for in the advertisement. Upon expressing their disappointment to the late Mr. A. S. Esslemont, one of the directors of Optical Munitions Supply, he undertook to invite all who were closely interested,

both in the R.F.C. and R.N.A.S., to meet me in his office in order that we might learn in what way one lens was thought to be better than another for aerial work. This was a most useful conference, for, although it was not then known why some lenses gave better results than others, the authorities were able to state the particular characteristics required in their negatives. These were wanted with as much contrast, and what was described as "relief effect" as possible, combined with very crisp definition throughout the whole field. These conditions were at that time to be produced by lenses of 8½-in. and 10½-in. focus at $f/4.5$ aperture on 5 by 4 plates. These results had appeared to be most frequently and easily obtained when using I. C. Tessar lenses, and we were challenged to produce a lens at least equal to, and, if possible, better than, this. We accepted the challenge, and every facility was given to have proper tests made. And here I desire to urge that in all new problems of this kind the optician should first be consulted and given the fullest knowledge of the requirements. With this information before us it was not long before we were able to submit our Aviar lens for trial.

When the lens was ready a stereo camera was provided by the R.N.A.S., an 8½-in. Tessar was fitted on one side, and our Aviar lens of similar aperture and focus on the other, and photographs were taken from an aeroplane with this apparatus at Farnborough. These proved to be very satisfactory, and

as our ex-President, Mr. J. H. Gear, stated last year, when he was asked to adjudicate upon the results, he had no hesitation in giving preference to the picture taken with the Aviar lens.

Now the task I have undertaken is that of explaining what improvement we were able to make in our lens to secure this result: but before proceeding I wish it to be clearly understood that in doing so I do not seek to belittle the Tessar, but to demonstrate how, in one direction at least, we have improved upon it.

Before referring to this in detail it is necessary to mention some of the points which have to be considered when designing a lens for a specific purpose. It is easy to construct a lens of small aperture giving good definition throughout a field of narrow angle, because the problems are in the main quite simple problems of chromatic and spherical aberration. But as the aperture and angle of field increase, the problem grows disproportionately in complexity because we have to deal simultaneously also with the further factors of astigmatism, coma, and flatness of field.

Therefore, if one requires the very finest definition over any

Fig. 1.

given field (or size of photographic plate), it is necessary in designing the lens to limit one's consideration to that size of field. Hence the importance of knowing the conditions; for, whereas an 8 $\frac{1}{4}$ -in. lens includes an angle of 20° from the axis on a 5 by 4 plate, a 10 $\frac{1}{2}$ -in. lens only includes an angle of 17° on the same plate. I shall presently show copies of two test photographs to illustrate the difference that can be made in field corrections by slight modifications of the lens.

But although improvement was made by correcting each lens for a specific angle, the more important improvement that I propose to refer to in detail resulted from a careful consideration of the coma corrections. One of our mathematicians, Mr. A. Warmisham, M.Sc., made a special study of this defect, hoping to improve upon the Tessar lens in this respect. This he succeeded in doing in his design of the Aviar lens. This lens is composed of two outside positive and two inside negative single elements, and may be considered as a modified form of Cooke lens, the coma correction of which is referred to in a book by Dr. Hans Harting, who says:—"Of the greatest importance is the good correction for coma . . . which corresponds to an equally good ful-

filment of the sine condition. In fact the Cooke lens is the first anastigmat which surpassed the anastigmats known at the time of its production in sharpness of definition over the usable angle of view. This was specially true for the series $f/4.5$, the calculation of which must be regarded as an absolutely brilliant achievement, the more so because the constructor had at his disposal to meet the eight conditions for the construction of an anastigmat a very limited number of elements of construction."

I would not convey the impression that perfection in a lens depends entirely upon its freedom from coma, but I hope that the consideration of this important factor will prove of sufficient interest to occupy the time at my disposal, and I will leave those who follow to deal with other defects.

It is probable that most here are familiar with the appearance of coma, but for any who are not I have made a rough diagram illustrating the comet-like shape that is produced by this defect upon small pencils of light which pass through a lens obliquely to its axis. (Fig. 1.)

Although coma is referred to as a separate defect, it is impossible to isolate it entirely from the kindred defects of astigmatism and spherical aberration. However, I will endeavour to do so as far as possible, and for this purpose have had a model made, which I show with apologies.

Imagine this (Figs. 2 and 3) to be a plano-convex lens with

Fig. 2.—Section through primary principal plane.

Fig. 3.—Section through secondary principal plane.

its optical axis at A, and that we wish to study the formation of an image of a distant point of light produced by an oblique pencil, or bundle, of rays limited in diameter by the circle at B. The centre ray of this pencil marked C is known as the principal ray, and our object will be to study the refraction of the rays passing through the plane formed by connecting this principal ray with the optical axis, *i.e.*, in the direction DCA, known as the primary or meridional principal plane; and also the rays which lie in the plane BCE, at right angles to DCA, and known as the secondary, equatorial, or saggital principal plane. This model will enable us to see what the section of the lens would be like in these two directions, and if we look at the last-mentioned first we see that the section is symmetrical about the principal ray, and therefore, whatever the result produced by the rays in this plane, it will be similar on either side of the principal ray. Now let us examine the section in the meridional plane, and we see that this is quite unsymmetrical on either side of the principal ray, which is, of course, common to the two planes. We should, therefore, expect the image formed in this direction to be unsymmetrical also, and therefore much more likely to cause trouble. If we were to study a section in all the other planes surrounding the principal ray, we should find none beside BCE in which the refraction would be symmetrical, and as

the image is built up of a multitude of rays passing through all these planes, it is easy to imagine that it is of a very complex character and difficult to analyse. While studying the formation of this oblique image it may be well to contrast it with the image of a distant point of light formed on the axis A of the lens. Here, of course, all meridians are the same, and the image is therefore symmetrical and free from coma, as all sections cut through the axis would be alike.

Before considering the subject in a more orthodox way by reference to diagrams, I have ventured to develop my illustration a stage further, and would ask you to imagine this to be the pencil of oblique rays, which we have been studying, converging to a focus.

If we now view the image formed by these rays we find it symmetrical about the principal ray in the second principal plane, but unsymmetrical in the first principal plane, producing the comet-shaped image with a bright nucleus of light and a tail-like fringe known as coma. You will readily understand that the coma at any given angle from the optical axis of the lens is the same in all parts of the field, assuming, of course, that the lens is accurately centred. This will be quite clear if I rotate the model on its axis.

Now to illustrate the same effect by means of diagrams, exaggerated to show this clearly, we will take first the case of rays passing through the lens from left to right which are parallel to the axis AB, and equidistant from it on either side. The rays CD will be refracted equally (Fig. 4), and converge

Fig. 4.

to a point G on the axis; similarly, the rays EF will converge to a point on the axis, but they are refracted more than the rays CD, and consequently meet the axis at a point H nearer the lens. It is well known, and I do not wish to spend time upon it, that this is the cause of spherical aberration, and this, so far as it can be dissociated from astigmatism, is what gives rise to any imperfect formation of image by an oblique pencil in the equatorial plane.

The next diagram (Fig. 5) will show the refraction of parallel

Fig. 5.

oblique rays through the meridional plane, in which AB is the principal ray, and it will at once be seen that rays equidistant and on either side of this do not meet upon it, but are differently refracted and produce a caustic curve, which is the cause of coma and the consequent want of crispness in definition where it exists. The intricate oblique image formed by a lens with coma consists of superimposed patterns of these two simple types.

The appearance of this coma will be clearly seen in the next

slide (Fig. 6), which will show actual photographs, magnified fifteen times, taken of an image of a small source of light in the local plane formed by Aviar and Tessar lenses of approximately the same focus and aperture, and under identical conditions.

The first image is that formed in the centre of the field,

Fig. 6.

i.e., on the axis of the lens, the next at an angle of 15 deg. from the axis, and the third at 20 deg. from the axis corresponding to the angle included at the margin of the field.

After what I have already said it will, I hope, be understood that what our lens designer aimed at was to so balance the curves of the Aviar lens as to secure as compact and concentrated an oblique image as possible with the minimum of

Fig. 7.

inequality in the fringe, and I am sure you will have no difficulty in agreeing with me that the set of images marked A produced by the Aviar lens is better in this respect than the set marked T produced by the Tessar.

The difference is also clearly marked in the next slide (Fig. 7), in which the images similarly produced by the same two lenses are focussed as accurately as possible. In this case the oblique images do not lie exactly in the focal plane.

The next slide (Fig. 8) will show the same results given by a normal Cooke lens. The absolute freedom from spherical aberration in the axial image, which, being common to both sets, is only reproduced once, and the really wonderful image at 20 deg. shows how nearly perfect the corrections of this lens

were, but the 15 deg. image indicates where improvement was possible.

Realising that photographs are not quite so convincing as seeing the actual images themselves, I hope to show these shortly, although it is difficult to produce them with sufficient brilliancy to show to so large an audience at once.

The next slide illustrates what I said in the earlier part of

Fig. 8.

my lecture about the importance of knowing the angle of field to be covered by the lens. These two photographs were made with lenses only slightly modified to alter the angle of best definition. In one case the middle zones are sacrificed a little to secure a rather greater angle, but in the other case, where the angle is not required, the definition is proportionately better at the smaller angles, although falling off very quickly beyond.

While the Cooke lens has always had very perfect axial

In the early days of the war we were already supplying lenses for aerial photography, but the conditions to be fulfilled had not been clearly realised by either aerial photographers or by lens makers, and naturally the commercial type of lens was recommended and used then. Although these lenses were excellent in their way, they suffered from a correction which had been driven too far—that is to say, the plate which these lenses covered was very much larger than that required for aircraft work, with the result that the edge of the plate came just into the position where the correction for astigmatism is at its worst. Photographers who use anastigmat lenses know that very often the image is better on the margin of the plate than in the intermediate zones between centre and margin. The actual magnitude of the astigmatism at its worst point generally is of the order of 0.5 to 0.6 mm. per 100 mm. focus; in other words, the aberration varies from 0 in the centre and margin of the plate to 0.5 mm. towards the lens in the intermediate zones. This generally applies to the very best anastigmat lenses which are corrected for covering angles of 56 to 58 degrees.

The first lenses supplied to Home and Allied Air Forces were of the commercial $f/4.5$ Xpres type, which were naturally corrected for angles such as we mention, but the results obtained on a 5 by 4 plate with an $8\frac{1}{2}$ or 10 in. lens were not as good as one would in the ordinary way of things expect, and investigation showed that the margin of the plate was just bordering on the region of worst correction. Knowing the excellent elements for correction in our Xpres lens, we felt certain that a modification of this type of lens would solve the problem in a satisfactory way.

corrections, it has been customary for most Continental makers to sacrifice central definition slightly in order to secure rather more covering power, but Mr. Twyman has recently demonstrated that by judicious figuring even this is no longer necessary, and it is fair to claim that the resolving power of the best photographic lenses has now reached a very high degree of perfection.

By the courtesy and assistance of officers in the lens testing section of the Air Ministry, I am able to show copies of photographs of their test chart, made with $8\frac{1}{4}$ -in. and $10\frac{1}{4}$ -in. $f/4.5$ Aviar lenses.

I have also their test of a $10\frac{1}{2}$ -in. $f/6$ Aviar lens designed to cover a 9 ins. by 7 ins. plate; and although from what I have said it will be understood that I do not consider comparisons between lenses quite fair unless they are designed for the same purpose, yet from the appearance of the next slide, made with a Goerz Dagor lens of approximately the same focus and with a slightly smaller aperture, it will be seen that considerable improvement will have to be made in this lens before it approaches the quality of the Aviar.

I have also some comparative test prints made with longer focus lenses which can be examined afterwards; for as time went on lenses of longer and longer focal length were asked for, and finally we made a 36-in. lens of the telephoto type; but subsequent speakers will refer in greater detail to these longer focus lenses.

It was at first sight a little unexpected that simultaneously with the demand for long focus lenses came a request for short focus wide-angle lenses. These were, however, needed for the purpose of securing photographs over a large area in order to study massed formation of troops, etc. That a 4-in. Cooke Primoplane lens should, from an altitude of about $3\frac{1}{2}$ miles, have produced such a clear, crisp image that barbed wire entanglements could be detected in the enlargements is, I think, a gratifying tribute to the quality of a lens of British design and manufacture.

W. B. APPLETON.

We therefore set to work to construct our $8\frac{1}{2}$ in. and 10 in. Airo Xpres, which aimed at the best correction of the image from centre to margin of the 5 by 4 plate. The larger foci, such as 14 in. and 20 in., were for correspondingly larger plates.

The general excellence of the photographs taken with these lenses shows that we have been successful in this. Whereas the commercial Xpres is corrected an angle of 56 deg., the Airo Xpres has been corrected for an angle of 36 deg. only, and conjointly with this the actual astigmatism has been reduced from 0.5 mm. to 0.25 mm. in the intermediate zones of the plate. This shows the great advance over the quality of the image of the commercial Xpres which has been obtained by the special construction of the Airo Xpres suitable for best performance on a small plate. Together with the correction for astigmatism, coma also has had to receive special attention.

The correction for coma, by which term we mean unsymmetrical spherical aberration of oblique pencils, generally becomes progressively worse as the covering angle increases, so that the image formed in the corner of the plate is an image composed of a first-rate astigmatically corrected image and a second-rate comatically corrected one.

The correction for coma has not generally received the attention that is really due to it. It has been frequently stated by noted authors of scientific works, Professor Harting, for example, that lenses that are well corrected for sine condition are free from coma. This contention we have not been able to substantiate; in fact, we believe that it does not hold

good in the case of photographic lenses of great aperture and substantial covering power.

We invariably find the zonal aberration of oblique pencils follows closely the zonal aberration of the central pencils; in other words, we find that a better coma correction can be got with lenses showing small zonal aberration for central pencils. The Airo Xpres is a good example of what can be realised in a lens which has all the elements necessary for the adequate correction of spherical aberration, astigmatism, and coma.

When engaged upon the manufacture of Airo Xpres lenses, the difficulty of glass supply became very acute, and we were asked by the Air Board to construct a lens that could be simply and quickly made of glasses in stock, and capable of reproduction by one of the English optical glass manufacturers. The outcome of this was the Ross *f*/6 Airo lens, a

type made of four single lenses, all dissimilar, but two kinds of glass only were employed—a light flint and a dense barium crown. Any mathematician who knows the difficulty of constructing a lens of such aperture and characteristics as specified by the Air Board, particularly when restricted to two types of glass only, will agree that this represents no mean programme.

It is a curious coincidence that the first photographs taken from an aeroplane were taken with a 17-in. *f*/5.4 Ross telecentric lens, and that the last lens we were engaged upon for the Air Board was a 36-in. focus lens with short back focus.

J. HASSELKUS.

(The paper contributed by Messrs. Aldis Bros. will appear next week.—Eds. "B. J.")

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
The Camera and the Lens (Jan. 10).
Managing the Sitter (Jan. 17).
Backgrounds (Jan. 24).
Studio Exposures (Jan. 31).
Artificial Lighting (Feb. 7).
Printing Processes for Portraiture (Feb. 14).
Studio Accessories and Furniture (Feb. 21).
The Surroundings of the Studio (Feb. 28).

Studio Heating and Ventilation (March 7).
The Postcard Studio (March 14).
The Printing-Room (March 21).
About the Reception Room (March 28).
Home Portraiture (April 4).
Portable Studios (April 11).
Copying (April 18).
Handling the Studio Camera (April 25).
More About Lenses (May 2).

ENLARGEMENTS.

I HAVE always felt that the majority of portrait photographers do not realise what an important branch of business may be made of selling enlargements if it is properly handled. Many of the present generation of receptionists do not seem to make any attempt in this direction, although there is often every opportunity of doing so, possibly because their attention has never been drawn to it, and partly perhaps for the lack of specimens of sufficiently attractive character. In most studios the specimens on show are more or less old-fashioned in style, and even if comparatively new are commonplace in style, resembling those which can be obtained from the cheap houses which specialise in this sort of thing. Some years ago photographers were troubled by a person named Tanqueray, who advertised free enlargements, afterwards demanding the sum, if I remember rightly, of 10 francs for packing and postage; but his activities here have long since ceased, and the legitimate trader has again the field to himself. The point is to offer something distinctive in character, so that it cannot be compared with work offered at a cheap rate. Most of the cheap enlargements are not of a quality which renders them fit to hang in a well-furnished house, and it should be the aim of the photographer to avoid this fault and to produce work that will not clash with such works of art as his patrons may already possess.

In my opinion every enlargement should be sent out framed appropriately, so that the work is not spoiled by unsuitable setting, and then one will not have such an experience as seeing a large red carbon vignette surrounded with three inches of crimson plush, which was once the fate of one of my own prints. It is, of course, wrong to force any particular style of frame or mount upon a patron, but if an intelligent interest is taken in his wants it is generally quite easy to produce something which is satisfactory both to photographer and

customer. Moreover, it gives the impression that the former knows his business, and prepares a favourable reception in advance. For instance, I always inquire where the enlargement is to hang—whether upon a light or dark wall, and the nature of any other pictures which are to be placed near it. This will often give the opportunity to suggest a more costly picture than the customer contemplated at first, which is all the better if he agrees. It is a little more trouble than showing the ordinary vignette on a light mount framed in two-inch oak, but it is worth doing, and if the customer does not bite there is always the "usual thing" to fall back upon. Many years ago Mr. Sarony adopted the plan of showing every likely sitter a transparency from one of his poses projected in the enlarging lantern, so that he could see what a fine picture it would make, and the financial results of this proceeding are said to have been eminently satisfactory. Most would not care to go to this length, but I mention it to show that it pays to take a little trouble to get a good order.

Besides the orthodox black and white or sepia vignette, there is a wide variety of styles in finishing, and it is well to be provided with a good range of specimens. Life-sized heads in monochrome framed close up are good sellers, as are those finished upon a tinted ground in imitation of crayon portraits. Good water-colour finish, or, what is easier and cheaper to produce, transparent oil colour, is also very attractive, while a solid oil finish, or even a painting upon canvas without photo-basis, will appeal to more people than most photographers would imagine. There are some firms who make a speciality of doing the latter class of picture from any photograph, and it would surely be better for the man who takes the original negative to have all that can be made out of it. There are plenty of good trade firms who will turn out first-class work, and artists who will paint direct at very reasonable rates, so

that there is no difficulty on that score. Few photographers have the time or facilities for doing the best class of work at home, and therefore often let opportunities pass by, supplying a two-guinea picture which they can make instead of a twenty-guinea one which could be put out. Even if the two guineas are nearly all profit it does not compare with what might be made out of the better class work. There are many West End firms who know what people are prepared to pay for a picture, but there are many more skilled photographers with a good class clientèle who are afraid to bring forward high-priced work. In what I may call a good middle-class business with which I was connected some years ago, enlargements and paintings were run on the lines I have indicated, and it was found quite easy to get a minimum of three guineas for 12 x 10, with prices ranging up to twenty-five and even fifty pounds for larger work, and this was at a time when three guineas a dozen was the top price for cabinets.

Naturally, for these prices permanency was guaranteed, and all the best work was upon a carbon or platinum; while bromide prints were always treated with a protective coating of wax to prevent the tarnishing of the image which would otherwise occur. It would be a good thing if bromide opals could again be brought into vogue, as these are naturally more permanent than paper prints, the backing being impermeable, while the surface can be protected. These are good selling points, something to justify the price which is asked.

Although portrait work provides the largest proportion of orders, it is surprising how much can be done in other directions. Horses and dogs are very remunerative lines, the former especially, as the owners are usually well to do, and will often order an oil painting if they find they can get it. I have taken £20 for a painting of a horse, not his own, from a man who has had a good win from it! It is necessary in such cases to avoid copyright troubles, but the owner of the negative will usually grant permission for a moderate fee, particularly if the work is to be painted without basis.

Coming into a different category, but still worthy of notice, are enlargements for commercial purposes, such as motor cars, buildings, silver ware, views for advertisements, and similar subjects. These will have to be made at very moderate prices, but here again quality must not be sacrificed to cheapness. If a man sells motor cars at £500 to £1,000 each, he is not likely to care whether he pays one guinea or two for a print, so long as he gets the best possible result from the subject. He wants either a fine view showing the car prominently or one in which the background is carefully blocked out, cast shadows put in with the air-brush, and all details clearly shown, and the man who will give him this gets the order. It is useless to treat such subjects as if they were amateur snapshots, just a straight print spotted and mounted. Do not think, however, that amateur work is to be despised; an amateur is often willing to pay well for a picture that will save his reputation. I have had one or two nice orders for Bromoids from negatives which were useless for any other process; the amateur got the credit for a work of art, and the photographer the cash.

Although this chat is rather a business than a technical one, a few practical notes will not be out of place. In the first place, especial care must be given to the quality of the negative, and where it is intended to try for enlarging orders all negatives should be made with that point in view. Fortunately a negative which is good for enlarging is good for all other purposes. A rather thin image is usually preferable, but it is not necessary. Full exposure should be given, and development must not be carried too far; all details should be clear in the high-lights as well as in the shadows; there should be no trace of fog, and to this end the dark-room illu-

mination should be carefully tested, and all reflections from camera bellows, lens tube, and other parts of the apparatus eliminated. There should be no trace of yellowness in the film, and for this reason it is desirable to use metol-hydroquinone or Azel instead of pyro, although with proper treatment pyro will give stainless negatives. It must be remembered that a patch of shadow without detail a quarter of an inch square will pass in a half-plate negative, but when this is enlarged to about four diameters it will be very evident. Similarly there must be no large patches of unrelieved white in the lights. There must be no need to apologise for the fact that the picture is an enlargement, and with proper methods there is no need that there should be. A careful selection of a suitable paper should be made. As a rule, I use rapid bromide paper, but with some negatives a slow paper, such as Vitegas, gives a far better result. It is not a waste of time to make a strip test so as to get absolutely correct exposure in the case of negatives thicker or thinner than the usual run, as this will save a second exposure on a full sheet, or remove the temptation to pass an enlargement which is not as good as it should be. I have known a man who had a reputation to keep to make half a dozen exposures before he was satisfied. With a strip test this should not be necessary. Do not economise in developing solutions. When large sizes are being handled the developer rapidly loses strength, and poor colours result. Fix thoroughly, moving the prints frequently to ensure even action, and wash thoroughly from one dish to another. These are not the methods used in making 20 x 16 for 1s. 9d., but they should be for high-class work. Of carbon and platinum enlarging technics I will say nothing, for I assume that anyone who undertakes this work knows his business; others should give it to a first-rate trade house, and they will not be disappointed.

As regards apparatus, for general convenience the ordinary type of lantern with condenser will be found the best, and as a general rule better quality is obtained by using a ground-glass diffuser between the light and the condenser, as this minimises the effect of retouching medium or tiny scratches on the film, especially when using an arc light. Probably the best results can be obtained by using daylight or arc lamp light reflected from a white screen, but this is not always possible.

The enlarging apparatus should have a permanent position, so that it is always ready for use, no time being lost in getting ready for work. It should, however, be examined before use, as lenses have a way of attracting dust, and if this is allowed to remain it means flat prints. Films should be sandwiched between two carefully selected glasses, free from scratches or bubbles, and if they do not extend to the rebate of the carrier, the margins should be protected by a paper mask. If black paper is not to hand, brown will do; even newspaper is better than letting a flood of light pass round the edges, as this causes a general fogging which is not always detected. Recently I was challenged on this point, and to prove my case I made two exposures, one with the edges clear and the other masked; the difference in quality was so great that I was surprised, although I had always practised masking. Michael Angelo, on being twitted upon his attention to trifles, said, "Trifles make perfection, and perfection is no trifle." I commend this dictum to all photographers, and to none more than to those who wish to make perfect enlargements. Slapdash methods may be successful to a certain point, but the best work calls for the exercise not only of intelligence but industry, and once one has got into the proper way of working it is no more troublesome than careless methods which frequently necessitate doing the work twice.

TRUE-TO-NATURE PHOTOGRAPHS.

Quite apart from any consideration of the artistic composition of a photograph, it must have been borne upon the mind of every photographer, or, indeed, on the mind of every one who carefully considers a photograph, that there is some relation between the distance of the object photographed, the focal length of the lens, and stop, which will give the most pleasing results. Further, the photograph can be viewed from a particular distance which may be better than any other.

It may not be everyone's opinion that what is termed a "true-to-nature" photograph is most pleasing to the eye, but a brief discussion of the matter is interesting, and in the writer's opinion throws some light on the reason why some photographs seem unnatural and perhaps displeasing. During last year the Department of Scientific and Industrial Research published a translation of Dr. Gleichen's "Theory of Modern Optical Instruments." In this book, among many other matters which it will repay the thoughtful photographer to study, is a discussion on the conditions which are essential to the theoretical "true-to-nature" photograph. It is the object of this article to present these conditions in a form which can be easily "understood by the people," and to make some comments thereon.

Now, Dr. Gleichen's definition of a "true-to-nature" photograph is one which, when viewed at a certain determined distance from the eye, will impress upon the retina an image in all respects as to size and definition in all planes, similar to the image produced upon the retina by direct vision of the object photographed. Dr. Gleichen states that two conditions must be observed, viz.:

(1) The entrance pupil of the objective must be equal in size to the entrance pupil of the eye.

Without involving any considerable error, we may substitute for entrance pupil of the objective the diaphragm or stop of the lens, and for entrance pupil of the eye the actual size of the pupil.

Now, the diameter of the pupil of the eye varies according to the light from 3 to 8 millimetres, consequently the diaphragm of the lens should be about 15 inch in diameter. No doubt it is to this condition that the artistic photographer will take the strongest exception.

(2) The equation $D = \frac{P}{B} + mL$ must be satisfied, where

D is the power of the lens or reciprocal of its focal length.

P is the reciprocal of the distance of the principal object of interest from the lens.

L is the reciprocal of the distance at which the photograph must be held from the eye.

m is the magnification to which the photograph may have been enlarged.

B is the lateral magnification at the entrance and exit pupils of the objective, which, since most lenses are symmetrical, will be taken as unity.

Hence the equation reduces to this form

$$D = mL + P.$$

It must be observed here that of course the same units of length must be employed throughout the equation.

This result at which Dr. Gleichen arrived may be presented in a form ready for instant solution by means of the annexed diagram, which links up the variables D, mL, and P.

The diagram consists of three parallel lines, I, II., and III.

On line I. is marked the focal length of the lens.

Line II. is marked in divisions giving values of mL, or the pro-

duct of the enlargement and the reciprocal of the distance which the finished photograph is to be held from the eye.

Line III. is marked with the reciprocal of P, or the distance of the principal object from the camera.

The use of this diagram is simplicity itself. A ruler laid across the three lines will cut each line at the precise value of the variable to satisfy the aforesaid condition.

For example:—A distant landscape is photographed with a lens of 10 inches focus. The line connecting 10 inches on line I. with the infinity mark on line III. cuts line II. at a value of 0.1.

Now for the normal eye 11. may be taken as 10 inches (the distance of distinct vision). Therefore m equals 1, and the photograph, if not enlarged, must be held about 10 inches from the eye.

Again, a photograph of a distant object is taken with a lens of 2 inches focus. The line in this case gives a value of mL of 0.5. If this photograph is enlarged 100 diameters on a screen $100 \times L = 0.5$, or $L = 1/200$, and the observer must be 200 inches, or, say, 17 ft. from the screen. If the enlargement be 200 diameters, the observer would have to be 33 ft. from the screen.

For a third and last example—An object 20 inches away is photographed by a lens of 5 inches focus. Here mL is 0.15, and it is seen that if m be taken as unity $L = 0.15$, and the eye must be held 7 inches from the photograph, or better, the photograph should be enlarged two diameters and held 14 inches away. It is interesting to observe that the diagram confirms the old rule that a photograph of a distant object should be viewed at a distance from the eye, equal to the focal length of the lens with which it was taken.

HARVEY COLLINGRIDGE, B.Sc.(Lond.).

FORTHCOMING EXHIBITIONS.

April 17 to May 22.—Hammersmith Hampshire House Photographic Society Annual Exhibition. Two open classes. Joint secretaries, J. G. Abrahams, 41, Hamilton Terrace, London, N.W.8; A. H. Page, 12, Laine Grove, London, W.12.

LIUT. A. F. LOVDAY, of the Photographic Section of the R.A.F., has been demobilised, and is now back at Holborn in charge of the Professional Department of Messrs. Houghtons, Ltd. 88-89, High Holborn, W.C.

LIUT. A. W. FIFE, R.A.F. Friends of Lieut. Tapp will be interested to know that he is now demobilised, and is returning to his civilian post of representative of Messrs. Thomas Blingworth and Co., Limited. Lieut. Tapp will call upon professional photographers only in London, the southern suburbs and home towns, the northern suburbs and home towns being worked by Mr. Craft, formerly manager of Blingworth's trade enlarging and printing department, which was permanently closed about three years ago. The dealers in London and suburbs will continue to receive visits on Messrs. Blingworth's behalf from Mr. Fred Giles, who has been "carrying on" with both dealers and photographers during the war.

TIME DEVELOPMENT WITH MONOMET-HYDROQUINONE.

A CORRESPONDENT having recently asked us for data and formulae for time development with Monomet-hydroquinone, the White Band Manufacturing Co. kindly send us the following particulars, of which no doubt many others than our enquirer will be anxious to make use:—

MONOMET-HYDROQUINONE: ONE-SOLUTION FORMULA.

Monomet	2 gms.	9 grs.
Hydroquinone	8 gms.	36 grs.
Sodium sulphite (anhydrous)	15 gms.	70 grs.
Sodium carbonate (anhydrous)	25 gms.	110 grs.
Potassium bromide	0.4 gm.	3½ grs.
Water	1,000 c.e.s.	10 ozs.

TIME AND TEMPERATURE FOR ABOVE DEVELOPER, WATKINS SYSTEM FOR PLATES.

75 deg. F.	1½ minutes.
70 deg. F.	2¼ minutes.
65 deg. F.	3 minutes.
60 deg. F.	4 minutes.
55 deg. F.	5 minutes.
50 deg. F.	6¼ minutes.

For VVQ plates, dilute 100 volumes with 125 of water.

For VQ plates, dilute 100 volumes with 70 of water.

For Q plates, dilute 100 volumes with 30 of water.

For M plates, multiply development time by 1.

For MS plates, multiply development time by 1½.

For S plates, multiply development time by 2½.

For VS plates, multiply development time by 3.

MONOMET-HYDROQUINONE: TWO-SOLUTION FORMULA.

(A) Monomet	2 gms.	45 grs.
Hydroquinone	8 gms.	90 grs.
Potassium metabisulphite.....	25 gms.	550 grs.
Potassium bromide	0.4 gm.	8 grs.
Water	400 c.e.s.	20 ozs.
(B) Sodium hydroxide (caustic soda)	15 gms.	330 grs.
Water	400 c.e.s.	20 ozs.

Take equal quantities of A and B, and dilute as required.

VVQ, dilute 100 volumes to 375.

VQ, dilute 100 volumes to 320.

Q, dilute 100 volumes to 280.

MQ, dilute 100 volumes to 250.

M, dilute 100 volumes to 190.

MS, dilute 100 volumes to 150.

S, dilute 100 volumes to 112.

VS, no dilution required.

TIME AND TEMPERATURE TABLE FOR TWO-SOLUTION FORMULA.

75 deg. F.	1½ minutes.
70 deg. F.	2 minutes.
65 deg. F.	2½ minutes.
60 deg. F.	3 minutes.
55 deg. F.	3½ minutes.
50 deg. F.	4 minutes.

For tank development, the above solutions may be diluted with a further quantity of water up to five times the original volume, and the time of development increased proportionately.

MEASUREMENTS OF PLATE-SENSITIVENESS TO X-RAYS.

COMPARATIVELY few investigators have published results of experiments on the sensitometry of plates to X-rays. A number of results, accompanied by a description of the methods used in obtaining them, were published in a paper by Millard B. Hodgson, of the Eastman Research Laboratory, which appeared in the "British Journal" of December 28, 1917. The following abstract of a paper by Miss N. C. B. Allen and Professor T. H. Laby, read before the Royal Society of Victoria last year, shows the value used by these experimenters in obtaining measurements of inertia, contrast, and speed of plates by sensitometric exposure to X-rays. The plates were developed in strips for a constant time of four minutes with hydroquinone developer at 68 deg. F., the density of a fog strip being deducted. The density measurements were made with a polarisation photometer. As the expression of the exposure the authors adopt the formula $\frac{V^2 i t}{d^2}$ where V is the pressure in volts

of the current supplied to the Coolidge tube: $i t$ in coulombs the consumption in current by the tube during a period of action of t seconds and d the distance of the focus of the tube from the sensitive plate in centimetres. The tube was employed at three different voltages—namely, 31,500, 75,000, and 83,000. Current variations ranged from 0.03 to 0.06 milliamperes. By plotting the densities obtained against the logarithm of the exposure according to the above formula the curve obtained was broadly similar to that produced in H. and D. measurements. In the case of densities ranging from zero to about 1.0 the curve exhibited convex formation towards the log exposure axis, then following a straight line to densities of about 4.0, which were the highest measured. By producing the straight line portion of the curve to meet the log exposure axis a point was obtained representing the logarithm of the inertia of the plate, a quantity which was found to be independent of development. Contrast was taken as expressed by the inclination of the straight portion of the curve, whilst "speed" is provisionally and empirically defined by the authors as the reciprocal of the exposure required to produce a density of 5.0. In comparing the results obtained with the different voltages ranging, as already mentioned, from 31,500 to 83,000, the authors found that for a constant "exposure" the density produced did not vary with the voltage so long as variation of i and t was small, indicating that in the case of the wave-lengths employed the density produced depends on the energy of the radiations but is independent if their particular wave-lengths. The following results are quoted:—

	Inertia.	Contrast.	Speed.
Diagnostic	71 × 10 ³	2.2	15 × 00001
Sonic	1.00	2.35	12
Seed	1.12	1.9	6.6
Wratten	1.95	2.2	5.2
Wellington	1.70	2.0	5.0
Imperial X-ray	1.26	1.6	3.6
Cramer	2.14	1.9	3.5
Ilford	2.19	1.9	3.3
Imperial S.R.	1.45	1.55	2.8

[Apparently the plates named are not all of them the special X-ray plates of the makers. Only two, which are known to us, are included in the table, and it is thus open to doubt whether the authors, in the case of the others, are referring to the "ordinary" plates or to those specially made for radiography.—Eds., "B.J."]

KODAK (AUSTRALASIA), LTD.

THE newspapers just to hand from Australia tell of the remarkable success of Kodak (Australasia), Ltd., which began as from June, 1908, with a small deficit representing preliminary expenses. It was formed nearly eleven years ago to amalgamate the Baker and Rouse and Australian Kodak interests. The Sydney "Bulletin" thus shows the progress of the business:—

Mar.	Profits.	Dividends.	Written Off.	Reserves.
1909.....	£22,038	9 p.c.=£11,250	£596	£9,714
Sept.				
1909.....	12,984	10 " " 7,500	358	14,840
1910.....	25,273	10 " " 15,000	3,869	21,244
1911.....	24,346	10 " " 15,000	3,067	27,523
1912.....	36,227	12½ " " 18,750	5,219	39,781
1913.....	36,890	12½ " " 18,750	5,238	52,183
1914.....	40,640	12½ " " 18,750	6,240	68,333
		Transferred to capital, £30,000		38,333
1915.....	54,228	15 p.c.= 26,250	5,852	60,459
1916.....	76,132	20 " " 36,000	6,538	94,053
1917.....	66,517	20 " " 36,000	6,657	117,913
1918.....	66,673	20 " " 36,000	5,942	142,644

The earlier profits were helped somewhat by the sale of assets—shares in the Eastman Kodak Co., of Rochester, U.S.A., for recent figures have not been swollen in that way. Since the war started, the Company has been on what our Anzac friends term "a fine wicket," partly because its Kodak connection guaranteed an ample supply of raw materials for the local factory. Further, when Uncle Sam got busy on war supplies, the American Kodak people passed their Asian and Maoriland business temporarily into Australian hands. The big increase in profits during the past few years has been due almost wholly to the greatly increased output of the factory, and the directors are given the following testimonial: "The policy followed during the war of increasing prices only when absolutely necessary has been continued; so that plates, papers, films, and cameras are still being sold here

(Australasia) at considerably lower prices than are ruling in England." Another view of Kodak's progress can be obtained from the following comparison, also from the business page of the "Bulletin":—

	1909.	1917.	1918.
Liabilities	£28,015	£59,531	£76,886
Freeholds	52,100	95,196	100,637
Plant, etc.	28,120	21,724	18,295
Stocks	33,135	166,541	181,745
Shares in other cos.	77,071	12,430	12,430
Book debts, cash, etc.	9,880	70,552	95,423

The Company started with a paid-up capital of £150,000, and shareholders have put up nothing further since, though capital has been increased by the transfer of £30,000 from reserves. In the nine and half years covered by the figures liabilities have increased by £48,871. Properties and buildings alone now stand in the books at £48,537 more, after the directors have clipped 2 per cent. off the value of the building each year—an unusual but wise proceeding. Meantime, £148,560 has been added to stocks and £20,902 to other more or less liquid assets, while plant, though extensive additions have been made, now stands at £9,825 less than formerly, owing to the very liberal allowances made for depreciation. Shareholders have done exceedingly well. On their original capital they have received in the ten years dividends totalling over 172 per cent., and even then there has been left in the business an amount some thousands in excess of the £150,000 capital they started with. Nowadays there are net assets of a book value of almost 37s. to represent each £1 share (including, of course the bonus shares); and excepting possibly stock (which, no doubt, has been accumulated at war prices), they are a particularly solid lot of assets. There are very few balance-sheets which indicate so clearly as Kodak's what the directors are doing in the matter of depreciation. Further, not a penny is represented by goodwill, trade-marks or processes, though at the moment they are undoubtedly worth a lot. The company lately acquired 120 acres at Kew (Victoria), where a model factory suburb is to be laid out.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Relative Proportions of Negatives and Enlargements

When making, buying, or selling enlargements, it is often useful to know beforehand exactly what size a standard negative will enlarge to without loss of some portion of the picture, also how much of a negative can be enlarged to a standard size without cutting down the paper.

For instance, we all know that a p.c. negative won't enlarge to 15 x 12 without losing some part of its length, but how many could say—without experiment—what it would go to on 15 x 12 paper, or how much of it could be included without reducing the width of the final picture?

The following tables give approximately the sizes that the most common negatives will enlarge to on standard sized paper.

They are extracted from a list compiled by the writer and used with benefit by a firm of trade enlargers.

Half-plate $6\frac{1}{2} \times 4\frac{1}{2}$ will enlarge to:—

$8\frac{1}{2} \times 6\frac{1}{2}$	on 1/1 plate paper
$10 \times 7\frac{1}{2}$.. 10×8 ..
$12 \times 8\frac{1}{2}$.. 12×10 ..
15×11	.. 15×12 ..
$20 \times 14\frac{1}{2}$.. 20×16 ..

To fill any of the above standard sizes from a half-plate, it is necessary to cut something from the end or ends of the picture.

Post Card $5\frac{1}{2} \times 3\frac{1}{2}$ will enlarge to:—

$6\frac{1}{2} \times 4\frac{1}{2}$	on $\frac{1}{2}$ -plate paper
$8\frac{1}{2} \times 5\frac{1}{2}$.. 1/1 plate paper
$10 \times 6\frac{1}{2}$.. 10×8 ..
$12 \times 7\frac{1}{2}$.. 12×10 ..
$15 \times 9\frac{1}{2}$.. 15×12 ..
$20 \times 12\frac{1}{2}$.. 20×16 ..

Postcard will not fill any standard size without losing nearly a quarter of its length.

While 5×4 will give:—

10×8	
12×10	(nearly)
15×12	
and 20×16	

it is too wide for half-plate and whole-plate, giving only:—

$5\frac{1}{2} \times 4\frac{1}{2}$	on $\frac{1}{2}$ plate paper
and $6\frac{1}{2} \times 8\frac{1}{2}$.. 1/1 plate ..

To fill these sizes it is necessary to lose a little from the sides of the negative.

12×9	c.m. will enlarge to:—
$6\frac{1}{2} \times 4\frac{1}{2}$	on $\frac{1}{2}$ plate paper
$8\frac{1}{2} \times 6\frac{1}{2}$.. 1/1 plate paper
$10 \times 7\frac{1}{2}$.. 10×8 ..
12×9	.. 12×10 ..
$15 \times 11\frac{1}{2}$.. 15×12 ..
20×15	.. 20×16 ..

Except with half plates, a 12 x 9 negative will lose in length if the paper is filled.

Quarter-plate, $4\frac{1}{2} \times 3\frac{1}{2}$ will enlarge to:—

$6\frac{1}{2} \times 4\frac{1}{2}$	on $\frac{1}{2}$ -plate paper
$8\frac{1}{2} \times 6\frac{1}{2}$.. 1/1 plate paper
$10 \times 7\frac{1}{2}$.. 10×8 ..
$12 \times 9\frac{1}{2}$.. 12×10 ..
$15 \times 11\frac{1}{2}$.. 15×12 ..
$20 \times 15\frac{1}{2}$.. 20×16 ..

Quarter plate is a shade long for all sizes except whole-plate.

$3\frac{1}{2} \times 2\frac{1}{2}$	will enlarge to:—
$4\frac{1}{2} \times 3$	masked p.c.
$6\frac{1}{2} \times 4\frac{1}{2}$	on $\frac{1}{2}$ -plate paper
$8\frac{1}{2} \times 6$.. 1/1-plate paper
$10 \times 7\frac{1}{2}$.. 10×8 ..
$12 \times 8\frac{1}{2}$.. 12×10 ..
$20 \times 14\frac{1}{2}$.. 20×16 ..

This size also needs the length trimming off before standard sizes of paper can be filled.

$4\frac{1}{2} \times 2\frac{1}{2}$	1A. F.P.K. film will enlarge to:—
$5\frac{1}{2} \times 3$	(masked p.c.)
$6\frac{1}{2} \times 3\frac{1}{2}$	on $\frac{1}{2}$ -plate paper
$8\frac{1}{2} \times 5$.. 1/1 plate paper
$10 \times 5\frac{1}{2}$.. 10×8 ..
12×7	.. 12×10 ..
$15 \times 8\frac{1}{2}$.. 15×12 ..
$20 \times 11\frac{1}{2}$.. 20×16 ..

No standard size can be filled by projection from a 1A. negative without losing over a third of its length.

$3\frac{1}{2} \times 2\frac{1}{2}$ (2 Brownie film) will enlarge to:—

$4\frac{1}{2} \times 3\frac{1}{2}$	(masked p.c.)
$6\frac{1}{2} \times 4\frac{1}{2}$	on $\frac{1}{2}$ -plate paper
$8\frac{1}{2} \times 5\frac{1}{2}$.. 1/1-plate paper
$10 \times 6\frac{1}{2}$.. 10×8 ..
12×8	.. 12×10 ..
$15 \times 10\frac{1}{2}$.. 15×12 ..
$20 \times 13\frac{1}{2}$.. 20×16 ..

This size is a shade long in proportion to standard papers.

$1\frac{1}{2} \times 2\frac{1}{2}$ (V.P.K. and O Brownie film) will enlarge to:—

$5\frac{1}{2} \times 3\frac{1}{2}$	(post-card)
$6\frac{1}{2} \times 4\frac{1}{2}$	on $\frac{1}{2}$ -plate paper
$8\frac{1}{2} \times 5\frac{1}{2}$.. 1/1-plate paper
$10 \times 6\frac{1}{2}$.. 10×8 ..
$12 \times 7\frac{1}{2}$.. 12×10 ..
$15 \times 9\frac{1}{2}$.. 15×12 ..
20×13	.. 20×16 ..

As to cutting out for filling the paper, V.P.K. is practically proportionate to postcard.

The above measurements are correct to eighths, but, of course, do not take into account possible shrinkage of paper or distortion due to want of parallel between the negative and paper during exposure.

THE EDITOR.

Photo-Mechanical Notes.

Buying Engravings Cheaply.

THE greatly increased prices of engravings has naturally incensed some purchasers, and there is a discussion in the current American "Photo-Engravers' Bulletin" on this subject. An article is quoted from "Advertising and Selling," in which the author describes several methods of avoiding payment of the prices fixed by the "standard scale" of the employers' association. For example, a charge is made for colour proofing. It is suggested that for simple work in two colours merely black proofs are sufficient, the second proof being made on tissue paper, which can be laid over the first proof to determine that the register is correct. With regard to minimums it is suggested that as many as possible should be put together and then sent to the printer or electrotyper to cut apart, thus saving the minimum charge for each block. Also, since photo-engravers charge for areas whether the whole area is filled or not, the purchaser should have his drawings made for a standard amount of reduction and fill in the spaces with his own drawings, just as the engraver fills in his "flat" by stripping-in different negatives into any spaces he has.

In reply, a photo-engraver points out that the charges of the standard scale are based on ascertained average cost, and that if all the devices mentioned were resorted to by the customer it would only mean that the prices would have to go still higher. He protests that the engraver should not be considered as a robber, but should be regarded as an ordinary business man who is fully aware that honesty is the best policy, and that if the customer goes to him expecting to get his work done in the most economical way having regard to quality, the engraver will, in his own interest, help him in his problems. If you cannot trust him, then do not go to him any more than you would to anyone else you would distrust, but you may be as confident of getting a square deal from the engraver as from anyone else whose services you buy, and this would seem to be a reasonable attitude.

No one would try to trick his dentist in the ways similar to those suggested, yet the dentist has for sale just what the engraver takes—namely, service. He manipulates a bit of metal which you take away with you when he stops a tooth, and the engraver does the same when he reproduces a picture, the value of the metal being fractional in either case. The only difference is that the operation of the engraver is more complicated, and, due to the customer wanting the result speedily, it has to be subdivided amongst several men instead of being carried out by one, but laboriously acquired skill is used in both cases, and it is chiefly the time expended in exercising this skill that must be paid for. One seldom hears of a dentist leaving a fortune, and a photo-engraver never.

Saving Wet Plate Negatives.

With the high cost of glass it is impossible to store negatives on the chance of their being required again, and it is very expensive even when there is a certainty. But there is no reason why negatives that will strip so easily as those made on wet collodion should not be saved. If a thick stripping collodion is used, or two coatings given, they may be stripped and kept between the leaves of a book. Certainly they are somewhat fragile, and are easily damaged, but with care they may be used over and over again. If a stiffer film is required, the negative may be placed on a levelling slab and flowed with a warm 10 per cent. solution of gelatine, which, when dry, will give the film considerable substance, or the plan has been adopted of stripping the film on to pieces of thin celluloid, when they can be handled as easily as an ordinary film negative.

Repeat Orders for Engravings.

If catalogue or other negatives are stored away under a proper indexing system they can be used for repeats, and so save the engraver the cost of making a new negative, and often afford the customer a quicker service just when he wants it badly.

The method of storing and indexing is as follows. Each job is given a number, and when finished this number is marked on the proof. The proof is now put in a classified file so that if an inquiry for an illustration is received again from the same customer—and some advertisers repeat the same illustrations over and over again, and believe in having original half tones rather than electrotypes—

the folder containing the proofs of all the engravings made of that article is examined, and if a suitable size is there the number is noted. The negatives, having been stored away under the same number in numerical order, can be found at once.

Rotary Photogravure from Flat Plates.

It would seem that sooner or later means will be devised for printing photogravure etchings which have been made on flat plates on the rotary printing machine, judging from the attention which inventors are paying to this subject. The great difficulty has been, of course, the joint. There must be some method of avoiding this joint showing on the printed result, and of preventing injury to the "doctor" blade which scrapes away the ink from the engraving. In a recent patent granted to Mr. Ruddiman Johnston he mentions no less than six British patents taken out with the same end in view. They are as follows:—14,819 of 1899, 25,050 of 1907, 13,153 of 1913, 4,018 of 1915, 10,550 of 1915, and 100,616 of 1916. Mr. Johnston's own patent is No. 117,888, and his proposal is to bridge the interval at the joint by a detached metal plate fastened to the cylinder to make it with the etched plate a continuous surface, and then to raise the doctor blade slightly when it reaches the junction by means of a cam so that the knife is not injured.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

- Applications, April 22 to 26:—
STUDIO ACCESSORIES.—No. 10,212. Photographic studio accessories and means for operating the same. E. J. Clayton.
VIEWING INSTRUMENT.—No. 10,325. Photographic apparatus for viewing, retouching, or copying. A. E. Morton.
PHOTOGRAPHIC SHUTTERS.—No. 10,414. Electrically-operated camera shutters. H. M. Batten.
FLASH LAMPS.—No. 10,413. Electric flash lamps for photographic purposes. H. M. Batten.
CINEMATOGRAPHY.—No. 10,441. Shutters for cinematographic apparatus. R. H. Bataille.
STEREO-CINEMATOGRAPHY.—No. 10,242. Stereoscopic pictures, cinematograph photography. J. Evans.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

PRINT TRIMMERS.—No. 124,173 (December 30, 1918). The invention relates to apparatus for trimming photographic and drawing papers, of the kind described in the specification of Merrett's patent No. 11,709 of 1908, provided with a fixed cutting shear and a pivoted cutting blade or guillotine knife, between which the paper or other material is cut.

The object of the present invention is to provide improved apparatus of this kind in which the cutting means are duplicated; that is to say, arranged with a shear and a cutter on each side of the apparatus, so as to produce at one operation two simultaneous and parallel cuts at adjustable distances apart. By the present invention it is possible to cut cards, paper, etc., along both sides simultaneously, the distance between the cuts being variable within the limits of adjustment of the apparatus.

In the drawing A represents the base of the apparatus, to which a table B is rigidly secured. On the under side of the table B is fixed a nut C, through which works a screw D rotatably mounted in a bracket C' on the underside of a second table B', secured to batons A' bearing against the frame A.

To each table is secured a fixed cutting shear E and a bracket

G, in which is pivoted a guillotine knife F, having a slight inward curve, and provided with a tail piece F¹, which is curved and bevelled as shown at F². On this curved and bevelled face F² normally bears a spring H which serves to keep the knife edge against the shear edge E during the downward movement of the knife and to return it to its initial raised position when the cut is finished. The spring H is pivoted at H¹ to the underside of the table so that it may be removed from the guillotine knife into, say, the dotted position, for convenience in packing the apparatus.

The two knives F are secured by loops, hooks, or the like

attaching means J' to a rod J carrying handles or the like holding means J'. K represents an ordinary graduated scale, which is secured to the base A for the purpose of determining the distance of the opening between the tables B and B'; L, L' are strips of celluloid or other transparent material; and M M are adjustment strips against which the forward edge of the paper or the like is pressed during the cutting along its sides. John Merrett, Trowbridge, Wilts, and Archie Thomas, 1, Adcroft Street, Trowbridge

MACHINE GUN CAMERA.—No. 123,999 (May 26, 1917). The camera is designed to provide means whereby marksmanship can be practised by means of photographs which can be exposed by the airman along an optical line parallel with and adjacent to what is normally the line of fire.

The invention thus comprises a camera in which the camera casing is of the form and dimensions of the magazine of a machine gun, the camera being adapted to be bolted in the usual position of the magazine to allow of photographs being exposed.

In the drawing, the casing 1 which may carry a lens tube 7, is in the form and dimensions of the magazine of a machine gun. The casing is bolted to the machine gun 2 in the usual position of the magazine. 3 indi-

cates the back sight, and 4 the front sight. These sights are adapted to give an optical line coinciding with the line of fire of the machine gun. The trigger release lever 5 is adapted to be operated by the trigger 6 of the machine gun to start clock-work mechanism, which is provided within the casing for actuating a sensitive film, so that it is passed across the shutter from a feeding spool to a receiving spool. Charles Duncan Miles Campbell (the late), Major, R.F.C., 17, South Vale, Upper Norwood, London; and Colin Martin Williamson, 23, Denmark Street, London.

CATALOGUES AND TRADE NOTICES.

BUTCHER'S ABRIDGED CATALOGUE.—Messrs. W. Butcher and Sons, Ltd., Camera House, Farringdon Avenue, E.C.4, have just issued a 190-page list of the many models of their hand and stand cameras, mounts, and albums, as well as of the other items of equipment of the amateur photographer. The list shows the very wide choice which is offered to the buyer of a camera.

THE ENSIGN 1919 CATALOGUE.—Messrs. Houghtons, Limited, 88 '89, High Holborn, W.C.2, have just issued a miniature edition of the goods of theirs in the way of cameras of all patterns, enlargers, and a host of minor accessories of interest to the amateur photographer. It is too early yet to look for new models of apparatus, but the list will be welcomed by amateurs (as well as by dealers), for whom the coming summer opens again the opportunity for photography.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

- SATURDAY, MAY 10.**
Huddersfield Naturalist and Photographic Society.—Excursion to Woodsome Hall.
- MONDAY, MAY 12.**
South London Photographic Society.—"The Negative." W. F. Slater.
- TUESDAY, MAY 13.**
Royal Photographic Society.—Ordinary Meeting. "Development Papers and Desensitisers." W. C. Mann.

Hodley and District Photographic Society.—Monthly Competition, "Clouds."

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, May 6, Mr. F. F. Renwick in the chair.

The President, Dr. C. Atkin Swan, gave a demonstration of carbon printing, of which no formal report can adequately represent the way in which the demonstrator worked, chatted, and joked through the technicalities of the process. Briefly sketching the historical development of pigment printing, Dr. Swan mentioned that the finishing touch to earlier experiments was put by his namesake, the late Sir Joseph Swan. They were not related, and as Sir Joseph Swan died the year after he, the lecturer, was born, he could not claim to have assisted him in his researches. He advised beginners in the process to buy the tissue ready sensitised. The makers charged the same for it as for the unsensitised tissue—he had never been able to understand why. The sensitised tissue required to be kept in a calcium box, and would then keep in good condition for a long time. A test of its condition was simply to soak a strip of it first in cold water for a minute or so, and then in hot water, when the pigment should dissolve entirely away, leaving a pure white sheet of paper, if the tissue was in working order. By means of a supply of printed tissues placed at his disposal by the Autotype Company, Dr. Swan demonstrated the operations of squeegeeing on to the transfer paper and of development. If one sensitised tissue oneself on a bath of potassium bichromate containing a little ammonia, the bath should be used at a temperature not lower than 55 deg. F. and not higher than 55 deg. F. He insisted that he always made it a practice to test the temperature of the sensitising bath with a thermometer, but in development he never used a thermometer, but gauged the advisable heat of the water by the rough-and-ready test of having it at a temperature comfortably warm to the back of the hand. At his invitation members of the audience came to the demonstration table and carried out the squeegeeing and development of prints themselves, a part of the proceedings in which Dr. Swan was assisted by his wife. The sensitising of tissue by the spirit method was also demonstrated. After the asking and answering of a few questions, the very hearty thanks of the meeting were accorded to the President by acclamation.

CROYDON CAMERA CLUB.

Messrs. T. P. MIDDLETON and F. W. KENT demonstrated "Kerotype Transfer Paper" last week, which received the full approval of a large audience. The paper has been previously described in the "B.J.," and consists of a gaslight or bromide emulsion on a translucent base, from which it can be stripped and transferred to almost any material.

Unless the sensitive surface is exposed through its support, the image on its final resting-place is, naturally, reversed. A slight loss of quality results in so exposing through the support, of no consequence with some classes of work if undesirable with others. In the latter case, double transfer is resorted to, which seems to present no difficulty. Thin films can, of course, be printed through the celluloid, and when enlarging all that has to be done is to present the glass or celluloid side of the negative towards the paper.

Luckily for the manufacturers, they can afford to laugh at familiar troubles occurring in the paper, for impurities are isolated from the emulsion by the impregnated wax. Consequently, a Kerotype print can be transferred to any paper selected, with no fear of those spots which lately have afforded many a professional cold feet and a warm vocabulary, as print after print has been thrown out, due to "metallics."

Notwithstanding, makers of bromide papers list a large number of papers of varying surfaces and weights, etc.—far too many, in fact—yet the list might be almost indefinitely extended and still a familiar type would not be satisfied, as the particular "shade of difference," which, in its opinion, "makes all the difference," would be bound to be absent. This type, usually, is not a paying proposition, but to such Kerotype will appeal.

In addition, although a small print can be applied to a large sheet of paper to give a picture surrounded with a white margin, probably at less cost than employing a large sheet of bromide paper, and masking (which procedure again dodges the aforesaid "metallics"), yet the chief appeal seems to be in the direction of transfer to what may be termed unusual supports, such as fabrics, wood, china, and glass. Many examples were shown, some pictures on white wood being particularly effective, as were others mounted, in crystoleum fashion, on the concave side of a large lens, and backed with white dental-plaster. One anchovy-paste pot with photo. on top made such a tasty knick-knack as to cause Mr. Harpur loudly to exclaim, "Won't mother be pleased!" And certainly the many pretty applications would have appealed strongly to the household, which chiefly acts as a setting to the pictorialist, receiving only reflected glory, apt to be unsatisfying. To those professionals who do not rise superior to side-lines of this order, the process is worth serious consideration.

Another point, if only a minor one, consists in the wide range of colours which may be obtained by toning, all methods applicable to lantern-slides being available. Some of these cannot be utilised for ordinary bromide papers, owing to the toning solutions precipitating in the fibres of the paper, causing a stain difficult, if not impossible, to remove.

At the conclusion of the demonstration, which was carried through in capital style, the president, Mr. John Keane, invited a discussion. This immediately elucidated that Mr. Walker was in trouble again. "What is the cause of this defect?" he asked; but the general laughter engulfed the answer. In reply to a question it was stated that the process was unsuitable for making transparencies (for enlarged negatives owing to a slight granularity becoming then in evidence. The reason for such granularity had not been traced. Mr. Salt suggested "reticulation" as the cause. Mr. Middleton said that was his opinion, but others thought differently. Mr. Jobling pointed out that he had frequently secured quite sharp bromide prints by contact, by exposing through the glass to an ordinary electric bulb placed four or five feet away.

It transpired that the lamp referred to was of ordinary type, and possibly a focus lamp without reflector might enable the distance and exposure to be reduced. With the "Pointolite" arc conditions for sharp prints would be ideal. Also, modern types of battery lamps run off accumulators, present a close approximation to a point source of illumination. Half-watt from four volts are now made. On the proposition of Mr. Sellors, who expressed his pleasure at a return to a technical subject, a hearty vote of thanks was accorded the demonstrators.

Commercial & Legal Intelligence.

LEGAL NOTICES.—Notice is given of intended dividends in the failure of Frederick William Gray and Margaret Jane Gray (joint estate), photographers, lately residing at Newlay Villa, Newlay Wood, Horseforth, near Leeds, and carrying on business under the style of the Empire Studios at 11, Queen Victoria Street, Leeds. Similar notice is given with regard to the separate estate of Margaret Jane Gray. Proofs must be lodged on or before May 13 with the trustee, George Henry Volans, incorporated accountant, 2, Albion Place, Leeds.

News and Notes.

LANCASHIRE SOCIETY OF MASTER PHOTOGRAPHERS.—A final reminder to members of the society is made of the exhibition which opens at the Art Gallery, Blackpool, on May 27. The latest date for receiving exhibits is Thursday, May 22. Exhibits should be sent direct to: Society of Master Photographers, Art Gallery, Blackpool. They will be returned carriage paid after the exhibition. The annual general meeting of the society will be held at the Palatine Hotel, Blackpool, at 2.30 p.m., on May 27, and the annual dinner at 5.45 p.m. on the same day.

"THE PROFESSIONAL PHOTOGRAPHER."—We welcome the reappearance, after several months' suspension, of our contemporary of the Kodak Company. The April number, recently issued, contains an appreciation of Mr. H. J. A. St. George, the newly elected president of the P.P.A., and of Mr. Peter Elfelt, of Copenhagen, reproductions of whose very individual portraiture are published; Mr. F. C. Tilney writes on the physiology of posing, and there are notes on halation and variety in background. The production in the matter of typography and illustration is of the high standard which has always marked the little magazine.

AN ALL-AUSTRALIAN NUMBER.—We have to congratulate Mr. Walter Burke on the production of an issue of his journal, the "Australasian Photo-Review," in which the whole of the text and of the illustrations is contributed by Australasians. The articles include one by Mr. W. R. Davidson on the employment of photography in railway construction work in New Zealand; others have for their subject the items of practical work, such as development, gaslight printing, and mounting, which interest the amateur of whatever latitude. It was in 1914, very unfortunately for him, that Mr. Burke announced his intention of issuing each year an all-Australasian number of the "Review," yet, despite the handicap of the war, which carried a large proportion of his readers to Europe, he has successively published five issues which very admirably represent the journalistic endeavours of his readers.

Correspondence.

REPRODUCTION FEES FOR PRESS PHOTOGRAPHS.

To the Editors.

Gentlemen,—Is it not time that the P.P.A. or the Press Photographers' Association took up the matter of the fee for reproduction of photographs in the Press?

At present the fee remains at the pre-war price, 10s. 6d. each under 6 x 4. Surely with the great increased cost of obtaining Press photographs—railway travelling, hotels, motors, wages, and materials—it is time that the usual fee was increased to 21s., or at any rate 15s.

If all the Press photographers agreed, as the plate-makers and other companies did, to increase the price, the papers could not object, for it must not be forgotten that the papers are increased in price.

I should like to have other photographers' views on this matter, particularly the Press agencies in London.—Yours truly,

A PRESS PHOTOGRAPHER.

SENSITIVE FERROTYPE BUTTON PLATES.

To the Editors.

Gentlemen,—We notice that in your reply to "A. L." in to-day's issue of the "B.J." you suggest that sensitive buttons are unobtainable, apart from any imported from America. May we point out that this is not quite accurate, as we have manufactured and supplied the sensitive button plates and discs for the last sixteen years. We therefore trust you will insert this letter to remove the impression conveyed that British users have to depend on foreign enterprise to meet their requirements.—We are, Yours faithfully,

p.p. The Quta Co.,

H. L. HICKOX.

252-256, Haydens Road, Wimbledon, S.W.

PRESS v. PROFESSIONAL PHOTOGRAPHER.

To the Editors.

Gentlemen,—“L. T. W.” is quite correct in asking for fairplay, but it comes rather as a shock to one who has been engaged in Press photography for a considerable period to hear that bona-fide Press photographers are guilty of such practices. I am under the impression, and a very strong one, that the camera man from Fleet Street is superior in his sportmanship to the so-called Press photographers who are annoying “L. T. W.” and others. At least this is my opinion of those I know, and I might mention that I am intimate with the cream of them.

In my opinion it is certainly most unfair if a man who is sent by a newspaper or photographic agency to do a job collars another man's picture which he has been “invited” (which, I presume, is the same as “ordered”) to take, and the photograph is used for any other than Press purposes. This raises another question also. Does not the professional photographer, at times, at public functions also encroach on the Pressman's ground by submitting his work to the Press. If he intends to compete with the Press photographer he must not be annoyed at his competitor's persistency. The Press photographer is sent out by his newspaper or agency to get pictures for Press purposes, and it is up to him to get the best pictures possible; but I do not think that any of his employers would sanction him doing anything that was not fair and square.—Yours truly,

C. W. B.

THE NEW STANDARD PLATE SIZES.

To the Editors.

Gentlemen,—According to remarks in the last two weeks' issues, I am under the impression that an attempt is to be made by the manufacturers of plates, acting in unison, to refuse to supply the professional photographers with plates in the “postcard” size and in the time-honoured quarter-plate size. I somehow feel that I am sorely labouring under a delusion. I am therefore writing to you to ask that the makers will be good enough to give us a clear understanding in plain words, and without ambiguity. There are thousands of photographers who have cameras, carriers, printers, and enlargers fitted for postcard-size plates, and thousands fitted for quarter-plates. Am I to understand that the plate-makers are combined together to prevent our obtaining supplies in these sizes, and by their “royal will and pleasure” we must give the “quietus” to all this apparatus, and sans question forthwith proceed to equip ourselves with new apparatus in sizes “dictated” by the firms who are kind enough to allow us the privilege of purchasing their manufactures, at their own prices, and do all this without demur. If this is so, it is a scandalous state of trade, and a crying injustice, and it chills the patriotic spirit of the times, which is “No Trade with the Enemy.” It may create a sense of retaliation that would welcome imported goods. There can be no tariff protection which shelters such “brigandage.”

The explanations as to the discarding of old sizes, in the manufacture of which they have made huge profits, are ridiculous. The motive is apparent, it is deeper. The majority of plates used are in postcard sizes, and it is their endeavour to compel us to use a larger size than necessitated for our purpose, at our loss and their profit. I take it you, as the organ of our craft, will give us opportunity to fully ventilate our grievance.—I am, Yours faithfully,

“25 Years a Plate-User.”

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

A. E. M.—You can get the vignettes from Mr. A. W. Bowen, 26, Dartmouth Park Road, London, N.W.

H. D. M.—No doubt Mr. R. E. Peeling, 6, Holborn Circus, London, E.C., will be able to supply what you want, or possibly undertake the repair.

D. T.—There is no doubt that the establishment of a studio comes within the Retail Businesses Order. The office to which to apply in your district is Queen's College, Paradise Street, Birmingham.

I. S.—The book by Ryland Phillips, “With Other Photographers,” was published some years ago by Messrs. Kodak, but is now out of print. You might be able to get it second-hand, say from Messrs. Foyle.

E. B.—A toning bath which has been exhausted by over-use or has been made with bad sulphide, or with sulphide the stock solution of which has deteriorated by storage, is the most common cause of such bad colour.

L. E.—There is no means of removing the effect of the intensification. We should judge that nothing can be done with the negative unless it is possible to work up a print or enlargement from it, and from that to make a new one.

L. S.—Photographic memorials of the kind you mention, made in brass, are supplied by Messrs. Hood, Limited, Middlesbrough; on porcelain by Mr. J. W. Beaufort, Easy Row, Birmingham, and the Farquhar Vitrified Enamels Co., Derby Lodge, East Sheen.

H. M.—A whole-plate lens ought to cover satisfactorily. Apparently your lens is not a good one. Your best choice would be an R.R. of about 9 in. focal length, such as a Ross Rapid Symmetrical or Dallmeyer rapid rectilinear, both good lenses, which you can buy for a pound or two second-hand.

W. S.—(1) The inquiry is too indefinite for us to give you a satisfactory reply. How do you wish to combine the prints. Perhaps you could send us a sketch of proposed arrangement. (2) An enclosed arc burns steadily, uses less current and carbons, and the light is of a much more actinic character than that of an open arc.

A. F.—Sixteen feet is rather short for ordinary work, and especially so for groups. For full-length cabinets the lens should not be of longer focus than 8½ in.; 5½ in. for full-length C.D.V. For groups on a half-plate, a lens of 6 or 7 ins. is the shortest which can be used, but we are afraid it would not be short enough.

H. H.—So far as we know, the Retail Businesses Order does not apply to Ireland at all. We have the text of the Order, but it mentions only Great Britain, and gives no address of an office in Ireland to which applications for licences are to be sent. So it seems pretty evident that no restriction of this kind applies to you.

C. B.—The firm have never made lenses, and we are unable to say now whether the R.R.'s issued with their name on them were made by a British or by a French maker. If French, the present

- value of the lens would be about £3. A 15 x 12 R.R., of about 21 to 21 ins. focus, if by Taylor, Taylor and Hobson, Ross, or Dallmeyer, has a value of from five to six pounds.
- M. M.**—Acid short stop is any bath which promptly arrests the further development of the prints through the action of the developer contained in the film. One such formula is 1 dr. of acetic acid to about 30 ozs. of water. Another is, say, $\frac{1}{4}$ oz. potass. metabisulphite in 20 ozs. of water. Another is sodium acid sulphite solution, say, $\frac{1}{2}$ oz. diluted to 20 ozs. of water.
- F. J.**—The licence applies to the business, not to the owner, and therefore there is no need to apply for a licence in taking over the existing business. The question of adding side lines such as picture-framing, is a debatable point, but in your particular case we should say that such a side-line is so very closely allied to the photographic business that it could not be considered a new retail business.
- S. N.**—If the condenser cell is nicked, it is probably in order that a thin bar, such as a steel rule, can be laid across in the nicks, and the one cell thereby unscrewed from the other. But if it is badly bound, very likely even that will not be enough, in which case there is nothing for it but to send it to some lens maker, who could make bosses to grip the two halves, and could possibly separate them.
- E. S.**—There is no other way of finishing high-class miniatures except the careful working in water-colours. A clever artist can do much with washes with the minimum of stippling. For the best work the carbon image is almost rubbed away before commencing work, but with cheaper qualities the carbon basis is left at full strength, and coloured in the usual way.
- H. A.**—We are sorry we do not know the suppliers of the Franklyn gloves. Judging from your description, they are for electrical work, and if you cannot get in touch with them through any local electric supply house, you might try the General Electric Company, Limited, 67, Queen Victoria Street, E.C., or a firm of dealers in aircraft supplies, such as Aircraft Equipment Limited, Long Acre, London, W.C.2.
- R. K.**—As stated in the review of the Brodrick drying cabinet, makers here have not produced apparatus of this kind. The only drying machines are American. The Kodak Company, Kingsway, London, W.C., supply one, but it is doubtful if they can now obtain deliveries from America. Another firm which has advertised apparatus of this kind in our columns is the Simplex Photo. Specialty Co., 337-339, East 34th Street, New York, U.S.A.
- P. G.**—(1) The No. 4 Busch portrait aplanat is 13 ins. focus. Pre-war price with iris diaphragm was £3. Current price to direct purchaser, say, £1 15s. to £2. (2) We have no particulars in our pre-war Busch lists of a rapid symmetrical. We should think it would be the same thing as the rapid aplanat of $f/8$, the half-plate lens of which is of 8-in. focus. Pre-war price was £1 15s. We should say that it would not fetch more than 10s. to 15s., as such R.R. lenses are fairly common.
- W. J. B.**—Special provision is usually made in the printing bed of a box printer for dealing quickly with film negatives printed with a white margin. There was a very simple and excellent device of this kind described with illustrations in the "B.J." of March 30, 1917, obtainable from our publishers, price 4½d. post free. You could easily adapt the idea of this to an existing printer, or you could use the masks sold for the purpose in all sizes by the firm of Artista, 5, Rue de Montfaucon, Paris, VII.
- S. W.**—There were two Warnerke sensitometers, the readings of which differed very considerably. It is, therefore, impossible to give an equivalent H. and D. number for the Warnerke degrees which you quote. The best we can say is that at the time the Warnerke numbers were used, say, 1880-1890, 24 degrees corresponded with something less than the fastest dry-plate then made. The fastest was 25 Warnerke. This would probably be only about 150 to 200 H. and D. as plates are now rated, in fact, we should say less than that.
- G. T.**—In so narrow a studio we do not think it would be desirable to have a movable frame for the lamps, otherwise your plan seems all right. It would be better to arrange the lamps in a curve, and you will not require any light so low as you have drawn it. The lights
- to the front of sitter should be from seven to eight feet from the ground, those at the side a little lower. We do not care for 2,000-c.p. lamps; the light will be better diffused and the exposures quicker with the same candle power in 1,000-c.p. lamps. These should each be fitted with a separate switch, as you will not always want them all in action.
- S. H.**—Your first step will be to make three negatives as equal in density as possible. Next make a strip test of each, developing for two minutes exactly. This will give you the correct exposure for each negative. Then get a large sheet of brown paper and cut an oval in the centre, large enough to vignette one bead at a time. Mark on the edge of the bromide paper where the centre of each head is to come. Make the exposures successively through the oval, taking care not to raise or lower the paper as you move it. Then develop for two minutes. If you do not get an even result on the first trial, the second will probably be all right.
- F. N.**—If the portraits were not ordered, that is to say, if you took them on speculation and it was optional whether the sitter ordered copies or not, then, unquestionably, the copyright is yours, and all reproductions of any shape or form are infringements of it. It is usual for sitters in such cases to sign a formal assignment of copyright, but that is not absolutely necessary since in any action evidence would show whether the photograph was ordered or not. If you have any considerable interests affected by this infringement, the best thing you can do is to put the matter in your solicitor's hands, and allow him to be guided by the little handbook, "Photographic Copyright," which our publishers issue, price 1s. 2d., post free.
- A. B.**—1. You do not name the town, so that we cannot tell you whether the Licence Office to which you should apply is the Hotel Windsor, Victoria Street, London, S.W. (for Kent, Surrey, or Sussex), or 5a, Union Street, Bristol (for Hants, Dorset, and Devon). 2. Yes, certainly a suitable camera, although cheap photographers as a rule do not go in for anything so elaborate. A yellow screen is of no service. 3. There were formerly white-you-wait cameras taking miniature, postcards, and larger sizes, but they came from America and are now practically unobtainable. No doubt you could get one second-hand by spending a shilling or so on a small advertisement. They were sold chiefly by the Chicago Ferrottype Company. You might also try Messrs. J. Fallowfield, 146, Charing Cross Road, W.C.2, or the Billeliff Camera Works, Richmond Street, Boundary Lane, Manchester.

SUMMARY.

Mr. L. P. Clerc, in a communication to the French Photographic Society, has identified the cause of white deposits in the drying of negatives with spirit as the precipitation of lime salts from the wash-water as a solid solution of themselves in the gelatine of the emulsion film. He has also worked out data which provide a working basis as to the number of plates or prints which can be dried with a given quantity of spirit. (P. 259.)

In the third of the papers, contributed to the Royal Photographic Society, Messrs. Aldin Brothers have recounted their achievements in the design and manufacture of optical munitions of war, including lenses for aircraft cameras. (P. 264.)

In a contributed article, to be completed next week, Mr. A. V. Godbold has some hints to give to the photographic colourist. (P. 261.)

The article by "Practica" this week deals in a general way with the means which a photographer having a studio in a town of medium size may take for obtaining business. (P. 263.)

At the Royal Photographic Society on Tuesday evening last Mr. W. C. Mann, chemist to Messrs. Thomas Illingworth and Co., read a short paper on the technical problem of avoiding desensitized spots in development-paper emulsion caused by mechanical impurities in the raw paper base. (P. 269.)

A remarkable case of reversal in tank development is brought to our notice by a correspondent. If any of our readers who have had a similar experience can throw light upon it, we shall be glad to hear from them. (P. 270.)

The British Photographic Manufacturers' Association, in the course of a letter amplifying their note published in our issue of April 25 last, make it clear that apprehensions are unwarranted as to plates for popular sizes becoming unobtainable. Even the change, on the part of camera manufacturers, from the present to the proposed standard sizes, is to be a very gradual one. (P. 271.)

In a leading article we have some hints to give on such minor repairs to cameras which properly come under the heading of renovations, and can be readily done by anyone possessed of the average handiness in the use of tools. (P. 258.)

Mechanism of film cameras and an improved pattern of folding pocket camera are among the patents of the week. (P. 268.)

Provision in the dark-room for the backing of plates is one of the factors which cannot be neglected without sacrifice of quality in the negatives of many subjects. (P. 258.)

A very practical method of introducing titles into view negatives is by assembling the view and title negatives upon a larger sheet of glass. (P. 258.)

EX CATHEDRA.

The Colonial Number.

It is evidently a sign of the more or less speedy return to fresh and rejuvenated national conditions that the announcements by British firms in the forthcoming Colonial and Foreign Number of the "British Journal" already assure a wide and important representation of the several divisions of the trade. In the case of some firms no doubt the inducement to advertise is small as a result of orders which have gone on accumulating for the past year or two, and which will call for some considerable time for their execution. Nevertheless, it is satisfactory to find that firms in this position, as well as those who can do with as much business as they can get, are recognising the value of the opportunity of bringing their name directly before the thousands of buyers in quantity of photographic goods to whom the issue is sent. But whatever may be the special circumstances of a firm, it is, we think, plain beyond the possibility of denial that the manufacturer or merchant who considers not merely the immediate future but the "long shot" is alive to the necessity of meeting foreign competition by keeping the resources and prestige of the British photographic trade before buyers throughout the world.

Developing Bromides by Time.

Despite the enormous number of bromide prints which are now produced, there is a comparatively small proportion of them which can be placed in the first class for quality. The weak point with most workers is incorrect exposure and in a smaller degree insufficient development, the general practice being to over-expose and under-develop. The first result of this is to produce prints which are not uniform in depth and colour, for the simple reason that unless developed singly it is very difficult to allow exactly the same period of development for each. If we compare a dozen bromides from an ordinary studio with a hundred printed and developed by an automatic machine we shall find much greater variation in the former than in the latter, because with the machine-made ones the exposures are all uniform and all have the same amount of development. Makers of bromide paper usually mention two minutes in a normal amidol developer as the time necessary to obtain a proper depth, but it is not uncommon to find printers giving thirty seconds or less. It may be imagined that more time is occupied if the development is carried on for the correct period, but this is not so, as more prints can be handled in the solution at once. If correctly exposed the action of the developer stops, and over-development is impossible. This can be demonstrated by anyone possessing such a machine as the Graber, which will evenly expose any number of prints which are afterwards developed in strips. We have seen a man handle forty or fifty strips in the developer at once,

and the results were quite uniform in colour. Exposures should be calculated to give proper depth with from two to three minutes' development, and for normal negatives there should be little if any bromide put in the developer. It is impossible to get rich sepia tones by any process on prints which are insufficiently developed, because there is not sufficient silver deposited to give the colour when turned into sulphide.

Titling Prints.

When large numbers of prints bearing a title or other wording are required the system usually employed by publishers, that of stripping the title from a special negative and transferring it to the subject negative, is doubtless a good one, but requires considerable practice to do it neatly, unless wet collodion be used for the titles, when the stripping can easily be done. An easier plan for the ordinary operator is to make his title or lettering on a process plate and to cut it and the view negative to the required size and shape, assembling them upon a sheet of glass, to which they are secured with lantern slide binders, or red paper and rubber solution. We have seen a souvenir card consisting of a title, a verse, and the signature of the poet, the latter copied from a letter treated in this way with a very happy result. One half-plate negative was taken of the title and verse, one of the signature, and these were cut and fixed above and below the view negative (also a half-plate reduced in width), which was direct from nature. The finished print was of whole-plate size showing a good margin. Although the original order was for a hundred copies only, the job was so well appreciated that in the end five times that number were supplied. When only a few copies are required it is quite easy to put in titles by double printing, which can be most easily effected in a printing box. To ensure correct placing of the title, it is necessary to make a pencil line on the back of the bromide paper while it is on the subject negative in the exact position the title should occupy, and to lay this line upon the title for the second printing. If a film manufacturer would give us thin celluloid, coated with process emulsion, titling would be much simplified.

Backed Plates.

Now that the season for outdoor work is again with us a word as to the value of backing plates for almost every class of subject will not be amiss. Nearly everyone uses backed plates for interiors in which windows have to be included, but many stop at this and do not think them necessary for ordinary outdoor work, with the result that, although there is no pronounced sign of halation, there is a general flattening of the lighting. This was perhaps less noticeable when slow plates with fairly opaque films were more generally used, but most modern rapid plates are inclined to be transparent and more liable to halation. It may be necessary to point out that this does not imply a lack of silver in the film, but only a difference in its condition. Unfortunately, the plate makers' price for backing has gone up in sympathy with that of the plates themselves, and this has led some who previously used backed plates exclusively to provide them only for exceptional subjects, a practice which often causes them to be out of reach when most wanted. Every dark room should contain a pot or tube of backing colour and a small sponge to apply it with; if diluted with methylated spirit it will dry so quickly that when half-a-dozen plates are wanted the first will be dry enough to put into the slide by the time the last is coated. Although the makers have now abandoned the red backing in favour of black, the red answers perfectly in most cases. What is needed is to destroy the reflective character of the inner surface of the glass,

and it is interesting to note that the white backing of the now defunct self-developing plates was quite effective. We remember seeing a photograph of an ordinary upright incandescent gas light taken on one of these without any trace of blurring.

MINOR REPAIRS TO APPARATUS.

In the preservation of photographic apparatus in a satisfactory working condition many little repairs can be done by anyone with no more than the average degree of handiness, and the delay involved in sending the apparatus away for repair thus avoided. As many of us well know, it is not the time actually taken by the professional repairer which deprives one of one's apparatus for so long a period, but the time which elapses before a particular job can be taken up in its proper place among other waiting orders. Therefore, we may usefully refer to some of the more ordinary defects to be found in cameras and other commonly used apparatus and give some indications of simple means of repair.

If the camera has experienced a good deal of use in damp weather out of doors, and has not always been thoroughly dried after use there is a tendency for the screws in its mahogany body to become loose or even fall out, a state of things which is the more likely to occur if the wood used in the first instance has not been fully seasoned. If it is a case simply of a few loose screws due to wear, it is quite an easy matter to plug the holes and thus obtain a firm hold for the screw. The best way to do this is to get a few odd pieces of cigar-box wood and, taking a small piece slightly larger than the whole diameter of the head of the screw, to whittle it down so that it will just fit tightly into the hole, the piece being given a slight taper. It is worth while taking a little care in order to get a good fit. The wood is then lightly coated with seccotine or ordinary glue and gently hammered into the hole as far as it will go. All the holes needing treatment in this way should be attended to and the camera put aside for the adhesive to harden thoroughly before the projecting ends of the inserted wood slips are cut off and the screws re-inserted. This is a far better plan than making shift with a larger screw, even when that is possible, which is not always the case, owing to the small aperture of any little brasswork fitting which is secured by the screw. We have even cured the same trouble occurring in the case of a blunt-ended screw having a worn thread on a small all-metal camera by cementing it in with fish-glue. On a field camera there is sometimes a tendency for the nuts and thread which hold the strut carrying the front and the reversing back to suffer wear at the point where strength is most required, that is, between the shoulder and the nut and the strut of the camera. A couple of brass or copper washers or burrs, such as are used when riveting, if placed between the nut and the strut will help to give a firmer grip unless the wear is very bad. In renewing worn brass screws a word of caution may be given. On no account should the screws be replaced by those of steel, or there is certain to be the occasion of regretting this trifling and false economy. We remember once fastening a lens flange to its panel with steel screws. In the course of time, during much outdoor use, the screws rusted in so firmly that when it was wished to sell the lens it was impossible to get the flange off without a certain damage to the lens panel.

Most probably any camera which had any long usage will require some repair work to the bellows. Pin-holes are best mended by sticking a piece of cloth, or, better still, thin leather, over the part. Black cloth is, of course, the most suitable, and an odd piece bought from a dealer

in book-binder's requisites will serve for a good many jobs. While this repair is in hand the bellows should be carefully examined with a view to discovering any worn places which may come to be a source of leakage without being suspected. If the bellows are very old, it is most probable that they will sag in the centre, especially if of any considerable length. It is not at all a difficult matter to make such serviceable for a considerably further period. Let the camera be racked out to its full extension and the bellows given a coating, inside, of very thin liquid glue. Great care should be taken to brush the liquid well into the folds, but it should not be applied too thickly or it will be a very long time in drying. Some people apply the glue also to the outside folds of the bellows, but it is susceptible to damp, and it is better to use copal varnish for the outside. The varnish can, indeed, be used for the inside, though not quite so good a stiffener. A few days at least should be given, with the camera fully extended, for the stiffening coating to dry. It may soon seem dry enough, but is liable to cause sticking of the folds when the camera is closed unless given the opportunity to become thoroughly hard. The inside should, of course, receive a fresh coat of dead black.

The amateur repairer is not recommended to undertake any jobs on shutters, at any rate, those of the between-lens type. To do so usually means more work for the professional repairer. The rubber bulb of the release can be easily tested for tightness by squeezing it under water and any part which shows leakage can be patched like a cycle tube.

The woodwork of the camera should have a careful polishing with a good furniture polish, taking care to avoid touching the lacquered brass fittings with the polish. Some brands of polish which we have used will remove

lacquer. If only field and studio cameras were regularly renovated by the photographer as though they were valuable furniture there would be fewer complaints of their failure to withstand any wear. Some of the apparatus that we have seen has been in a disgraceful condition, woodwork dull and lacking in polish, even clammy with overmuch handling. No wood is like mahogany for showing every mark upon its surface, but a good occasional polishing and a frequent rub over with a dry, soft cloth and chamois leather will do much to keep its good appearance and condition.

Dark-slides which are not perfectly light-proof are a source of constant apprehension to their user. We are all of us familiar with the operator who needs to hold his slide rolled up in the focussing cloth until the very last minute, and even while inserting it into its groove feels the necessity of carrying out manipulative feats in order to prevent possible admission of light. The most likely source of leakage is the division between the two halves of the slide, due to shrinkage of the wood through rapid drying after exposure to a damp atmosphere. A way to remedy matters in this respect is to cement a layer of fairly thick black velvet along the edge of the slide round all four sides. This will make the catches hold more tightly as well as provide a trap for any entrance of light. We have several times repaired book-form slides in this way, and have had no trouble from leakage of light afterwards. If the hinged flaps on the shutters are worn they may be renewed with small strips of leather cloth or book-binder's cloth cemented over the previous one. It may not sound a good plan, but we have used it many times. Usually there is ample room in the cut-off of the slide for the very little extra thickness which the leather cloth represents.

DRYING WITH SPIRIT: THE CAUSE OF WHITE DEPOSITS AND THE DRYING EFFICIENCY OF SPIRIT.

[M. L. P. Clerc, who, during the greater part of the war, has taken an active share in the Photographie Section of the French aerial service, has made the following contribution to the "Bulletin of the French Photographic Society." It will be seen that problems arising from the employment of photography upon different parts of the Western front have been shown, on investigation, to have a very direct relation to those met with in ordinary indoor work where alcohol is used for the rapid drying of negatives.—Eds., "B.J."]

In almost all the sections employing aerial photography in conjunction with the French army service there cropped up at one time or another the production of a white opalescent deposit between the glass and the gelatine film of negatives hastily dried after immersion in an alcohol bath. The defect was often marked upon parts of the plate which were the first to dry, and particularly showed itself after long immersion in undiluted spirit followed by rapid drying with the aid of heat. The defect has frequently been attributed to the inferior quality of the spirit which was used, but it is produced just as easily when the pure alcohol is employed. It is entirely due to the salts of lime in the wash water, and has been found to occur most readily in those sections of the army occupying parts of the front in a chalky or limestone region, such as Artois, Picardy, Champagne, and Woivre.

Bicarbonate of lime, which is present in all waters (with the exception of distilled water and freshly collected rain water) is a salt which is regarded as necessary for rendering a water palatable, but on evaporation it leaves carbonate of lime, forming the chief part of the incrustations on boilers and of the fur in kettles.

When the negative is dried without having previously been

immersed in alcohol, the gelatine prevents the precipitation of this carbonate of lime, which, thus protected, forms with the gelatine a transparent homogeneous mixture, that is a solid solution. It is known, moreover, that colloids, of which gelatine is the most perfect type, are able to confer the colloidal state upon substances which otherwise would not assume it.

But bicarbonate of lime, while soluble in water, is completely insoluble in alcohol, and the white turbidity which is formed when alcohol is diluted with ordinary water is due to the precipitation of this salt. Now, when a negative is placed in alcohol before having been left to dry, there is a tendency for the precipitation of carbonate of lime from the water with which the gelatine is impregnated, but if the replacement of the water by the alcohol is not complete the protective part played by the gelatine is still exhibited by a retardation or a prevention of the precipitation, at any rate up to a point of sudden upset of the equilibrium by very rapid drying.

This precipitation may be compared with the formation of a grain by the drying of the familiar ground-glass varnish, consisting of a solution of resins in ether, to which a small proportion of benzole has been added. The benzole alone does

not dissolve the resin, and added in excess would precipitate them from their solution in the ether. On drying, the ether, which is the more volatile of the two liquids, is the first to evaporate, and thus leaves an excess of benzole, which precipitates the resins as a grain. A varnish without benzole would leave a transparent film; a varnish containing a large proportion of ether gives a very fine grain, particularly if the drying is very slow; whilst a varnish containing much benzole, or one which is dried too rapidly, gives a coarse grain. It will be seen, therefore, that there is a certain resemblance to the formation of the deposit of lime salts by alcohol.

On the one hand, the deposit is not produced in negatives which are rinsed in distilled water, however long they may be immersed in fresh spirit; on the other hand, the deposit is produced as readily with pure alcohol as with denatured spirit, which shows that the cause of the deposit lies in the water employed for washing. If the deposit is due to the precipitation by the spirit of bicarbonate of lime, soluble in water but insoluble in alcohol, it should be possible to produce the deposit under other experimental conditions, using any salt which is soluble in water but insoluble in alcohol, such, for example, as carbonate of soda.

Three plates (fixed and washed) were soaked in a 1 per cent. solution of carbonate of soda. One of them, A, was left to dry spontaneously; another, B, was soaked for ten minutes in a spirit bath which had become somewhat diluted by previous use, and was then put to dry in a moderately warmed room; the third plate, C, after immersion for ten minutes in the same spirit bath as that used for B, was soaked for a further ten minutes in fresh alcohol, and then dried before a good fire. The periods of drying were respectively one hour, half an hour, and five minutes. Plate A is perfectly transparent; plate B shows only a very slight deposit, and that existing in the corner of the negatives which was highest in the draining rack, and thus dried the first; the plate C has the appearance of an opal glass.

In order to avoid with certainty the formation of this white deposit on negatives dried with alcohol, it is necessary either to use a water free from lime salts, such as distilled water, rain water, or water which has been treated with a disinfectant, or to convert the bicarbonate of lime which is contained in the gelatine into a salt, which is soluble not only in water but also in alcohol, immediately before placing the negatives in the alcohol.

Now, the chloride, nitrate, and, to a lesser degree, the acetate of lime are soluble in alcohol, and are immediately formed when carbonate of lime is brought into contact with a solution (which may be a very dilute one) of a corresponding acid. The immersion of the negatives immediately before putting them in the spirit in a weak bath of hydrochloric acid (10 c.c.s. of commercial acid to a litre of water) suffices to avoid the formation of the deposit on drying.

Sulphate of lime, like the bicarbonate, is present in almost all waters, and is also insoluble in alcohol, but it is generally present in smaller quantity than the bicarbonate. Moreover, it is much more soluble in weak solutions of hydrochloric or nitric acid than it is in pure water, the solutions thus acidified giving no precipitate on addition of alcohol. The immersion of the negatives in weak hydrochloric acid thus provides a preventive of precipitation of this compound.

It should be understood that the acid solution should be liberally used and frequently renewed in order to avoid any saturation of the acid by the successive introductions of the lime salt.

In cases where the omission of this precaution or its improper application should have allowed the deposit to be formed, subsequent treatment requires to vary according to the character of the deposit. If the deposit covers a fairly

large surface of the negative, the latter should be passed through a bath of the diluted hydrochloric acid and dried again. If the deposit exists simply as a patch of small area, it will disappear by directing the breath upon it for a few minutes. The carbonate of lime re-dissolves under the action of the moisture and carbon dioxide of the expired air.

A question of some importance in the drying of negatives with spirit is the effect of the strength of the spirit upon the duration of drying. After having found that the time of drying of a negative treated with spirit is almost independent of the time of immersion in the spirit when this latter is greater than ten minutes, we investigated the effect of progressive dilution of the spirit on the time of drying, the period of immersion of the negative in the spirit being kept constant at ten minutes. For this purpose gelatino-bromide plates and papers of 13 x 18 cm. size were fixed, washed, and then placed respectively in denatured spirit of 90 degs. used in admixture

Proportion of water in 100 vol. of spirit.

Fig. 1.

with water, so that the proportion of water to 100 parts of spirit ranged from 10, 20, to 90 parts. After allowing five minutes for draining, not included in the time reckoned as drying, the plates and papers were left to dry spontaneously at a constant temperature of 64 degs. F., away from air currents, each plate placed alone on a draining rack and each print hung freely by a string without having been blotted. The results of these tests are shown in the curve, Fig. 1, where the curve A corresponds with plates and B with papers. Plainly no absolute value can be attached to the times thus determined, since in all drying operations the quality and thickness of the gelatine and the conditions of drying are variable quantities. But it is seen that the effectiveness of spirit as an accelerator of drying falls off very quickly as the solution is diluted, the times of drying being relatively to that of drying after treatment with fresh spirit, doubled when the spirit contains 20 per cent. of water.

It remains to discover approximately the number of negatives or prints of a given size which could be treated with a given volume of alcohol at this dilution, which is considered as the practical limit in the use of alcohol. In order to calculate this number, ten 13 x 18 cm. plates and ten 13 x

18 cm. sheets of bromide paper were fixed and well washed. After washing, the plates and papers were drained and the wash water collected and weighed. Plates and papers were then weighed first wet, then after complete drying. The figures obtained were as follows:—

	One plate 13 x 18.	One sheet 13 x 18.
Weight, wet	83.8 gm..	7.5 gms.
„ dry	81.0 „	4.7 „
Water absorbed.....	2.8 „	2.8 „
„ drained	3.8 „	2.5 „

From these figures, and assuming that after ten minutes' immersion in the spirit bath equilibrium is established between the liquids in and outside the gelatine, assuming also that

Fig. 2.

the volumes of alcohol absorbed by the plates or papers are respectively equal to the volumes of water above determined, and neglecting any evaporation of alcohol, we calculated, for an initial volume of three litres (3,000 c.c.s.) of alcohol, the progressive dilution for each plate or each sheet of paper according to the three methods of handling:—

A. The plates or papers are taken roughly from the last wash water into the alcohol bath, without intermediate draining, and removed quickly from the alcohol bath, the drainings of alcohol being lost.

B. The plates or papers are drained before immersing in the spirit, but not on removal from the spirit, the latter drainings being lost.

C. The plates or papers are drained before and after immer-

sion in the alcohol, the spirit drainings being collected and returned to the spirit bath.

Comparisons made by means of an hydrometer between the spirit bath after use, according to the different conditions just mentioned, together with observations of the numbers of negatives or prints and of the dilutions at which the alcohol was used, have shown a satisfactory agreement between calcu-

Fig. 3

lation and practice, the same denatured alcohol and the same wash water being employed. Diagrams Figs. 2 and 3 show the numbers of negatives or prints thus determined, in particular the dilution limit (introduction of 20 parts of water per 100) is reached after treatment of:—

EXPERIMENTAL CONDITIONS.			
	A.	B.	C.
Plates	102	200	240
Papers	135	250	305

Comparison of these figures emphasises the practical advantage of draining negatives and of draining or, still better, of blotting prints before and after their treatment in the spirit bath, and spirit drainings being returned to the latter bath. A more economical employment of the process is obtained by passing negatives or prints successively into two spirit baths, the second of which thus becomes diluted very slowly. The dilution of the first bath may then reach as much as 50 parts of water per 100 before it needs to be replaced by bath No. 2, and the latter by fresh spirit.

L. P. CLERC.

FOURTEEN POINTS ON COLOUR.

1. PHOTOGRAPHERS in the near future will have to interest themselves in the question of colour, if they are not doing so, as it is such an important element in portraiture, and as regards handwork is practically the monopoly of professionals, and a line, if it is given due consideration, which will enhance the profits. There are plenty of middle-class people who can afford, and wish for, a truthful portrait in colour if it can be done without a lot of fuss and bother to themselves. Workers of the future will be earning more money, and are already taking more pleasure in their homes, and will want portraits with an added charm.

2. Colour has been called the sunshine of art, as it assists wonderfully in the expression of beauty, but unfortunately its use and application do not seem to be governed by laws, as in the case of composition and light and shade. If we turn to books on colour they not only demand a lot of time for study, but they are too theoretical to be easily understood, and it seems difficult for an artist to get help out of them in their present form, or

to be able to refer to such books for a scheme of colour for a particular purpose like one can refer to B.J.A. for a formula. The greatest difficulty in arranging a colour design is the qualities and quantities of colour entering into a scheme of harmony. These and several other points are not dealt with in books on colour, for the simple reason that a number of fine specimens are required to display what cannot be given in words; therefore I should like to see a colour theatre or college established in London for displaying fine specimens, for lectures, latest results of colour photography, colour organ displays, and other items of interest to artists, designers, florists, etc. As it is, artists practically have to teach themselves by studying appearances and referring to acknowledged portrait masterpieces. Fortunately there are plenty for our guidance, as colour is the quality which has contributed to their preservation.

3. "There is one quality of good colour," to quote Professor Church, "which lies at the very root of all successful employ-

ment of vivid hues. It consists in minute variations of hue and tone within the same surface. A colour must not be absolutely uniform, flat and monotonous unless it be very pale, very dull, or very dark when the absence of this 'throbbing' or 'palpitating' quality, though undesirable, is less observed. We have before us as we write a fine old Chinese vase of turquoise crackle. Apart from the mosaic texture, resulting from innumerable fissures in the glaze, what a number of variations in appearance does this turquoise colour offer! Where the colour is thinnest it is paler and verges more upon green; where it is thickest it is at once deeper and more blue, and there are innumerable hues and tones. In painting similar effects may be produced by unequal glazings and scumblings of one hue upon another." What artists sometimes call "accidental" colour, only got by mixing colour on the palette—the airbrush is too mechanical to give it—an unconscious picking up and applying of tints gives this play and is, no doubt, what Whistler had in his mind when he explained "that it was impossible to produce the same masterpiece twice over—as difficult as for a hen to lay the same egg twice."

4. The influence of design on colour can only be explained by showing the same pattern in various schemes of colour. In making a complex colour arrangement it is well to begin by planning first its leading parts, the additions will then be easier. The colour of an object may be beautiful, but much of that beauty may be lost or neutralised by its surroundings. Harmony of colour must come not alone from the object we are planning, but also from the person who is to wear it. As an example, take a man's portrait dressed in black and seated, colour it and make the background a rich blue, then show it to a critic, he will at once say: "Bad colour, background comes too forward, looks cheap, the face appears leathery, etc." But you use the same blue on a lady's coat trimmed—collar, cuffs and flounce—with black velvet, and show it to the same critic; he will say, "Who's the lady?" which means he is interested, and it is pleasing.

5. If you have strong contrasts of colour the contrasts of tone between them must be small. The Japanese often made the most successful use of violent contrasts of colour by being careful that they should be the same tone value. And again, where you have strong contrasts of tone, such as Rembrandt was fond of, you cannot successfully have strong contrasts of colour as well. If Reynolds wished to paint a lady in a dress of gold silk with a blue background he made a compromise by making all the shadows of the dress and accessories a brown colour to keep a harmony in his work. It will be found in nature that her general colour scheme is divided into warm and cold colours. Harmony arises from the reflection of one colour upon the adjoining, so as to produce a blending, interlacing of the various hues, producing a chain of connections between the extremes of hot and cold. The practise of this was the success of the Dutch school. The colour of flesh indoors is cool in the lights and warm brown in the shadows. It is said Delacroix

was so surprised to find, when his model put his head out of the window he was a different colour: that flesh showed its true colour in the open air with cool violet shadows. A portrait does not depend upon a number of little touches, but upon the big relation and differences of warm and cool colours simply employed. Whistler obtained his harmonies by employing tone and variations of a limited number of colours.

6. Photography is remarkable for the ease in which gradations of tone melts imperceptibly into each other without strokes, lines, dots, or scratches, therefore—as every material speaks its own language—it is not advisable to destroy by sloppy brushwork, its chief characteristic, but to maintain this and the high-class appearance of the paper that manufacturers strive to supply. Those who can admire bold brushwork over the exactness of a photograph can enjoy a drum accompaniment to a mandoline. Students turn to books on painting for assistance, and get led astray about brushwork, which rightly belong to oil and water-colour sketching from nature. Why try to hide the photo base when experts can easily detect it?

7. Compare Gainsboro's thin painting, which is esteemed for beauty and freshness to Hogarth's heavy, solid paint. Rembrandt's early work is smoothly painted, and quite as vigorous as his late and much rougher style. The vigour of effect depends on truth of tone, of light and shade, not on thickness and roughness of paint.

8. The colourist has definite colours for the face, dress, and hair, the background being left entirely to the artist's skill, and as so much depends on the importance of the colour support, it is hoped the following will be helpful. As some sort of guidance to a student, it is pointed out that great masters very often made use of the small interval of colour, like Velasquez's "King of Spain"—the coat is black and the background black. Holbein's "King Henry VIII."—the coat is light blue against a darker blue background. Leighton's "Moretta"—the dress is apple green against an olive green. Millais' "Bubbles" is green velvet against olive brown. These are just a few thought of at random. It is impossible to give rules, but the general tendency is a complementary colour behind the figure, and its contrasting colour in front. In some of the old masters the background is gray, the coat black, and the waistcoat yellow. With ladies this is easier to arrange if the background is greenish and the dress red, the contrast is by means of a string of blue beads. If a little of the colour of interest is repeated in the background it links the parts together. The use of a contrasting colour separates the subject from the background. If you are compelled to use contrasting colours which do not perfectly harmonise, a way out of the difficulty is to mix a little of each colour with each other. Say a bright red dress and a full green background take a little of the edge off the green with some of the red and carry a little of the green into the shadows of the dress. This method, with other strong contrasts, should give an improvement.

(To be continued.) A. VERNON GODBOLD.

SHEFFIELD AND DISTRICT PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.—A meeting was held on May 7 in Stephenson's Café, a fair number of members being present. After passing the minutes of the last meeting, a discussion took place on the proposal of the Ministry of Labour to train discharged officers and soldiers with a view to becoming proprietors of photographic businesses. After a long discussion, the matter was left in the hands of Mr. Gould, who originally brought up the subject for discussion, that he might gather more information on details which were at present doubtful. A very interesting topic then brought forward was "The Best Method of Studio Artificial Lighting for Portraiture." Half-watts, Marion's Northlight, the Westminster and Jandus arcs, and mercury vapour all had champions, and some very interesting opinions were heard. The subject was so interesting that "last-car" time came when arguments were still unfinished, and the theme will be further pursued at the next meeting. The Association welcomes new

members. The hon. sec.'s address is 137, Pinstone Street, Sheffield.

PHOTOGRAPHIC NAVAL WAR RECORD.—Arrangements are being made by the Admiralty for a permanent exhibition in the Imperial War Museum of a complete photographic record of every ship of both the Royal Navy and Mercantile Marine employed during the war, together with a series illustrating, so far as is possible, every incident of interest or operation with which the sea forces were connected. The Admiralty invite any member of the public, and especially officers and men who have been demobilised from the R.N., R.N.R., and R.N.V.R., to contribute photographs or negatives, depicting subjects of interest from the naval point of view, which have been taken during the period of hostilities at home or abroad. The Director, I.W.M. Photographic Depot (Naval Section), 12, Coventry Street, W.1, will consider photographs or negatives submitted.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
The Camera and the Lens (Jan. 10).
Managing the Sitter (Jan. 17).
Backgrounds (Jan. 24).
Studio Exposures (Jan. 31).
Artificial Lighting (Feb. 7).
Printing Processes for Portraiture (Feb. 14).
Studio Accessories and Furniture (Feb. 21).
The Surroundings of the Studio (Feb. 28).
Studio Heating and Ventilation (March 7).

The Postcard Studio (March 14).
The Printing-Room (March 21).
About the Reception Room (March 28).
Home Portraiture (April 4).
Portable Studios (April 11).
Copying (April 18).
Handling the Studio Camera (April 25).
More About Lenses (May 2).
Enlargements (May 7).

ADVERTISING THE STUDIO.

I ASSUME the object of everyone who starts a photographic business to be that of making money. To make money you must get orders, and to get orders you must announce to that section of the community whose patronage you seek that you are willing to serve them. An American humourist has said that trying to do business without advertising is like winking at a girl in the dark: you know what you are doing, but nobody else does. As competition increases, advertising becomes more and more necessary, and we can prove this by referring to any old newspaper of twenty-five or thirty years ago. Then one found no drapers' advertisements; now we find the most prominent positions, even whole front pages in the great dailies, occupied by people in this line of business.

Now, the first thing the photographer has got to realise is that although he may be an artist he is also a tradesman. Not only photographers, but many painters and sculptors suffer either from a lack of knowledge on this score or a false pride which will not allow them to recognise the fact. I know more than one painter of great ability who has a hard job to make ends meet because they are retiring men who are incapable of elbowing their way into "society" and getting talked about. Let it not be imagined that I recommend any artist, whether photographer or painter, to degrade his art by pandering to popular taste, against his own instincts, but to place of his best boldly before the world and await results.

There are a few photographers who have made a name in the way usually followed by artists—that is to say, by being present at any public function or social event to which they can obtain the entrée, and by sedulously seeking introductions to all who may be useful to them; but this way is obviously not open to the majority, who have to cater for all classes, and must attract attention in a more businesslike way. As the superior person would put it, they must stoop to the practices of the tradesman.

In the first place, I take it for granted that a photographer has established himself in a locality congenial to his own tastes, for if this be not so the cleverest advertising will not avail him. A man whose natural venue is Bedford Park will be hopelessly out of his element in Bow; and so with many other places.

An error which is made by many people who should know better is to start advertising before the goods are ready for delivery. Much money is wasted every year in this way; therefore, it is necessary to see that everything is in full running order before seeking publicity. Nothing is so disappointing to a would-be customer as to arrive at a new studio and to find it still in the hands of the decorators. I well

remember a lesson which a friend received in this way. He had advertised the opening of his studio in an effective way, and when the most important lady in the locality came for a sitting he had to explain that owing to some unforeseen difficulty his studio camera and lens had not arrived from London. He offered to take her with an outdoor outfit, but she was accustomed to good-class London studios, and she indignantly declined. He eventually made good, but considered that the loss of prestige which he sustained through this occurrence cost him more than a delay of several weeks in opening would have done. The necessity for observing such things is shown by the fact that a business man with no knowledge of photography can start studios and build up a large trade by employing operators, while a clever photographer may wait in vain for sitters.

There are many factors in making a business which may be classed under the heading of advertising. The premises themselves are the first. When Mr. Selfridge came to London to start a drapery business in competition with the most celebrated firms in the trade, he did not take the first commonplace looking building which would have provided the necessary accommodation, but erected a building of unique design in the position which he considered the most suitable. We cannot all do this, but where it is a question of choosing between convenient premises of poor appearance and situation and those which are less convenient but in a position likely to attract custom I should unhesitatingly choose the latter. We can, with a little ingenuity, rig up an unsuitable place, but we cannot get people to go a step out of their way until a very good reputation has been established for the business.

The next important factor is an attractive series of specimens in styles which can be supplied without modification or delay. A photographer cannot show samples of his work in the newspaper advertisements, so that the least he can do is to show them on his premises, and, in addition, in as many showcases as can be placed in eligible positions. Railway stations have long been popular for this purpose, and deserve their popularity, for people waiting for trains have time to look at the show, and if the case is clean and bright there will usually be spectators in front of it. The choice of platform is important. In most stations the departure side for the largest town is the best, as people have usually to wait for trains to arrive; when they get to their own station they lose no time in getting away. Booking office positions are of little value, as people do not linger there. I have found showcases at local post offices and hairdressers to yield a good return, and for exhibiting these the proprietors will usually accept payment in kind. Wherever the cases may be, they

should be well cared for, and the specimens changed frequently, or they will cease to attract attention unless in an undesirable way.

Much has been said and written as to the value of circular or personal letters addressed to former sitters and other desirable folk, but their value depends much upon local conditions. It is doubtless a good plan to keep in touch with those who have already patronised the studio, but letters to strangers are usually connected with free-sitting offers, and I advise that this class of business be left alone. A well-known photographer who had gone in for it extensively said to me: "For twenty years I have been spending thirteen pence to get a shilling without knowing it." People do not value what they can get for nothing unless they are of a certain class who will take all they can get on the cheap, and those who intend to pay for photographs prefer to go where they fancy the work. One of the most progressive and prosperous men in the trade never gives a free sitting even to popular actresses, and gets as much business at good prices as he can deal with. As a contrast to this I can instance a case where a photographer agreed to take free a hundred sitters from a Government department for a presentation album, trusting to re-orders to recoup himself. The amount of these was £4! The publicity gained in this way does not seem to be worth much, the only exception perhaps being in favour of the local papers, where an occasional paragraph can be obtained in return for services rendered. Newspaper advertising is expensive, and, as far as I have found, gives a poor return, although if paragraphs can be inserted, at advertisement rates, referring to any recent achievements, such as photographing the mayor or local M.P., or any local event, it will usually be worth while.

In small towns much may be done to promote business by personal action, such as taking part in any popular movement, serving on committees, joining any suitable societies, and in every way showing activity and business ability. People will then realise that you are one of the institutions of the place,

and come to you as a matter of course. Although most photographers do not realise it, the friendship of local amateurs is worth cultivating. These folk can seldom take a decent portrait, and are more likely to send their families to a man who sympathises with them than to one who has given them a snub.

The best advertisement of all is a satisfied customer, and if you ask many people how they get their sitters they will say, "By recommendation"; and there is no easier or better way when this can be done. To do it requires much tact, for one dissatisfied sitter will do more harm than half a dozen satisfied ones will do good. It is not so much a question of the quality of the work as of treatment. If there is any question of a re-sitting it is wise to give in gracefully, and not to let the party go away with a feeling that he or she has been harshly dealt with. People who are habitual "kickers" must be dealt with firmly but courteously. Their word, as a rule, does not carry much weight, as their own friends know that they are never satisfied; but even they should not have to complain of rudeness.

A modest piece of advertising which is usually remunerative consists in the distribution of small calendars bearing a specimen photograph of a child, dog, or other attractive subject. The calendars can be purchased very cheaply, and the prints made and mounted at odd times.

There is nothing very novel in the foregoing remarks, but as they are the result of personal experiences of my own, and close observation of the doings of others, I trust that they will be of some value to those who have to make a start without skilled advice. Always keep your performances up to your advertised promises. I remember one firm which put up a big sign which read: "What we say we do, we do do." This is an excellent sentiment to live up to; unfortunately the firm who put it forth did not justify their slogan, and soon closed down. Nothing, perhaps, is more resented by people than failure to keep promises.

PRACTICUS.

THE DEVELOPMENT OF BRITISH LENSES FOR AIRCRAFT PHOTOGRAPHY.

[The third of the papers contributed to the Royal Photographic Society and reprinted from the Society's "Journal" is that setting forth the share taken in the provision of lenses for aerial photography by the Birmingham firm of Messrs. Aldis Bros. That Messrs. Aldis were not longer and more largely associated with the supply of this optical munition of war was no fault of theirs. The resources of their factory, as will be seen from the paper, were taxed to the utmost in the manufacture of certain other equally essential optical instruments.—Eds. "B.J."]
